10/4/18: Michel's clips removed; wound perfectly healed. 28/4/18: Splint removed; movement of joints free. 28/5/18: Getting about on crutches; no shortening of limb. 28/6/18: Allowed to walk without aid. 6/8/18: Radiograph shows firm union, with plate and fragments in excellent position. 22/8/18: Radiographed; shows perfect bony union, and no trace of the break. 27/8/18: Returned to duty, a most satisfactory result.

CASE 21681.—Admitted to hospital 6/3/18 with fracture of left tibia and fibula. Whilst at work on the railway a sleeper accidentally fell on to his left leg, causing the above injury. He had previously to my seeing him been treated in a box splint. Shortening of limb 1 in.

---

[1] A series of excellent radiograms accompanied this article and fully bear out the statements in the text.—ED. L.

X rays showed fragments to be in very bad position, with outward displacement of the lower fragments of both tibia and fibula.

9/4/18: *Operation*.—Longitudinal incision 9 in. long to the outer side of the crest of the tibia. Muscles separated from the tibia and the site of the fracture exposed. A fair amount of callus had to be chiselled through. The ends of the fragments were cleaned ready for apposition. Before doing this a separate incision over the fibula was made, the bone and fracture exposed, and the callus uniting the fibula in the malposition chiselled through. It was then quite easy to bring the tibial fragments into apposition. This being done, a plate was screwed on, the tibia being in excellent alignment. No plate was put on the fibula. Wound closed with Michel's clips.

21/4/18: Clips removed; primary union. 6/5/18: No shortening of limb. 18/5/18: Massage; patient allowed up on crutches. 18/6/18: Walking with aid of sticks only. 30/6/18: Walking well and painlessly without aid. 28/7/18: Patient walking normally. He has never complained of any discomfort or disability whatever since the operation. 5/8/18: Returned to duty.

CASE 6724.—Admitted to hospital 13/3/18 with ununited fracture of left tibia and fibula (1/9/17). Whilst attending machinery he was caught in a revolving lathe, whirled round, and then thrown violently to the ground, fracturing left tibia and fibula and the right humerus, radius, and ulna. Taken to a hospital in Boulogne for six months, where the humerus, radius, and ulna united perfectly with excellent functional result. On admission the left leg was in plaster. This being removed, the tibia and fibula were found to be ununited; there was a pressure sore on the heel of the left foot, and another one over the lower end of the upper fragment of the tibia. Operation was deferred until the pressure sores were quite healed.

25/4/18: *Operation*.—A longitudinal incision 9 in. long was made ¼ in. to the outer side of the crest of the tibia, the bone exposed, and the muscles separated. The ends of the fragments were rounded and eburnated. There was a slight amount of callus between the apposing lateral overlapping surfaces of the tibia, but none from the ends, the foot being quite flail. The ends were sawn off. Through a separate incision over the fibula this bone was exposed and found to be in the same state as the tibia, the ends rounded, and no callus thrown out. The ends were sawn off. Then the tibial fragments were brought into perfect apposition and a plate screwed on holding them in good position. A plate was also put on to the fibula. The wounds were closed with Michel's clips and the limb put on a back splint with a foot-piece.

9/5/18: Clips removed; wounds perfectly healed. 16/7/18: Radiographed; shows excellent position of bones. 26/8/18: Walking without pain and without aid. 10/9/18: Plate on fibula removed as it was subcutaneous and in the way of a boot, the upper rubbing against it. 16/10/18: This has been a most satisfactory case. When he came he had no union, had been unable to put his foot to the ground, and was confined to bed. Now he walks perfectly well, with no pain or discomfort. 18/10/18: Discharged to duty.

CASE 45619.—Fracture right tibia and fibula. Admitted to hospital 21/6/18 with history of a piece of wood having fallen out of a lorry on to his leg, causing a transverse fracture of both bones at the junction of the middle and lower thirds. X ray showed transverse comminuted fracture of tibia and fracture of fibula at the same level, lateral displacement, and antero-posterior bending.

8/7/18: *Operation*.—Incision to outside of crest of tibia 9 in. long, exposing the bone. At the site of the fracture there was a large triangular-shaped piece of the tibia broken right away from the bone, from the external and posterior aspects, just where the plate should be fixed. The ends of the tibia were cleaned and brought into good apposition, and a plate applied and screwed on over the triangular broken piece, which was held in position by the plate, but no screws were driven through it. The wound was closed with Michel's clips and the limb put up in a Thomas splint with extension.

15/7/18: Michel's clips removed; wound healed, primary union. 20/7/18: Thomas splint replaced by a short back splint with foot-piece. 20/8/18: Splint removed. 22/8/18: Radiographed. X ray shows parts in excellent position and quite a fair amount of callus formation. The triangular piece of bone, which was completely severed, is in excellent position. 8/10/18: Radiographed; very satisfactory result shown. 30/10/18: Getting about and helping in the ward. 2/11/18: Discharged to duty.

CASE 28572.—Fractured right tibia and fibula. Admitted 31/5/18. While attending a water-cart it tipped up and fell on patient's leg, causing a fracture of the right tibia and fibula. X ray. Radiograph shows transverse fracture of tibia and fibula at the same level, at the junction of the middle and lower thirds, with inward displacement of the lower fragments. There is also some comminution of both bones.

8/7/18: *Operation*.—The tibia was exposed through a longitudinal incision external to the crest and the fracture exposed. Some soft callus was chiselled away and the ends brought into excellent apposition. Plate applied to external surface and screwed on. Wound closed with Michel's clips and limb put up in a Thomas splint with extension. With a view of obtaining a good result without operation this fracture was treated in a Thomas splint with extension for a month. Extension was continuous and adjusted every day, yet at the end of a month there was still shortening and malposition of fragments.

17/7/18: Clips removed; wound perfectly healed; kept on splint. 22/7/18: Thomas splint removed, back splint and foot-piece applied. 23/7/18: Radiographed; parts shown to be in excellent position. 5/9/18: Right knee-joint found swollen, not painful. Aspirated, 2 ounces clear straw-coloured fluid removed. 8/9/18: Stereoscopic radiograph shows tibia in excellent position. 16/11/18: Radiographed; as above. Measurements both legs equal. 28/11/18: Discharged to duty.

CASE 4807.—Admitted 28/6/18 with transverse fracture of left tibia and fibula only 1½ in. above the ankle-joint, caused by foot being run over by a light railway truck.

10/7/18: *Operation* 12 days after the accident; very much displacement of parts. Small plates were put on both tibia and fibula. The plate applied to the tibia had to be bent so as to conform to the curvature of the bone. Both tibia and fibula were brought into perfect apposition. Wound closed with Michel's clips. Limb put up in a Thomas splint with weight extension.

18/7/18: Michel's clips removed; wounds perfectly healed. 26/7/18: Thomas changed for back splint with foot-piece. Movements of joints carried out. 19/8/18: Back splint removed; knee- and ankle-joints freely mobile. 2/10/18: Allowed to get up and walk with aid of crutches. 21/1/19: Discharged to duty. Limb as sound as the one unbroken, no shortening and perfect union of fragments, no break being visible in the X ray.

CASE 130213.—Admitted 28/6/18 with transverse comminuted fracture of the right tibia and fibula, injury five days previously, lower fragments displaced outwards.

12/7/18: *Operation* 19 days after the injury. The ends of the broken tibial fragments were cleaned of intervening tissues and brought into good apposition. On the postero-external aspect a triangular piece of the tibia was broken right off, being quite separated from the bone. This was replaced in position and the plate applied over it, though no screws were driven into it. The fibula was exposed through another incision, and a small amount of callus already formed chiselled away and the ends brought into perfect apposition and a plate applied. The wounds were closed with Michel's clips and the limb put up in a Thomas splint with extension.

20/7/18: Michel's clips removed and wounds perfectly healed. 22/7/18: Thomas splint substituted for back splint with foot-piece. 19/8/18: Splint removed; movement of knee- and ankle-joints perfect. 2/10/18: Allowed up and to walk with aid of crutches. 25/11/18: Getting about without stick or crutches. 21/1/19: Discharged to duty. The limb is the same length as the other; no pain, no disability of any sort, and the point of union of the bones has disappeared, and the medullary cavities are normal.

CASE 37651.—Admitted 19/8/18 with transverse comminuted fracture of the right tibia and fibula 2 in. above the malleoli, the lower fragments being displaced inwards.

28/8/18: *Operation* ten days after the injury. Longitudinal incision along outer border of crest of tibia. Fragments exposed and brought into perfect apposition. Plate screwed on to outer surface of tibia, holding the fragments in excellent position. Wound closed with Michel's clips. Limb put up in a Thomas splint with weight extension.

7/9/18: Michel's clips removed; wound perfectly healed; limb put up on back splint with foot-piece; movement of joints carried out. 28/11/18: Allowed up on crutches. 28/12/18: Up and about, no stick or crutches being used. 21/1/19: Discharged to duty. Limb as sound and useful as uninjured one; no shortening, no lameness, no disability of any kind. An excellent result.

CASE 92666.—Fracture right tibia and fibula. Admitted to hospital 12/8/18 with history of being struck by iron crane while working on the wharf at Dieppe. Radiograph showed very nasty comminuted fracture of both tibia and fibula, with much displacement of fragments, the lower fragments displaced outwards.

10/9/18: *Operation.*—Longitudinal incision to outer side of the crest; fracture exposed. Great difficulty was encountered in getting the fragments into good position on account of the amount of comminution of the posterior aspect of the bone at the site of the fracture. Plates applied and screwed on, holding the fragments in a very good position. Wound closed with Michel's clips. Limb put on back splint with a foot-piece. The skin was broken near the wound, but this was avoided.

22/9/18: Michel's clips removed; wound perfectly healed; movement of joints carried out and limb replaced on splint. 30/11/18: Commencing to get up on crutches. 5/12/18: Radiographed; tibia and fibula in perfect alignment, with excellent callus formation; medullary cavity in fibula commencing to be formed. 13/1/19: Radiographed; excellent result. The site of fracture can still be seen in the lateral view only. 10/2/19: Radiographed; excellent result. 12/2/19: Discharged to convalescent ward.

TOPOGRAPHIC PERCUSSION AND VISCERAL TONICITY.

BY ALBERT ABRAMS, A.M., M.D., LL.D.,
LATE PROFESSOR OF MEDICINE, COOPER MEDICAL COLLEGE (STANFORD UNIVERSITY), SAN FRANCISCO, CALIFORNIA.

IN a recent communication,[1] "L'orientation des animaux et les influences magnétiques," by Jules Regnault, before the Society of Comparative Pathology, the following observation is made:—

> "My studies on orientation have been controlled by the observation of Abrams. To obtain the best results subjects must stand on a grounded plate and colours and intense light avoided. Under these conditions my investigations with colleagues at Vichy, Granville, and Toulon show the following: When the heart area was defined by percussion (patient facing west), then percussed again with the patient facing east, north and south, the area of dullness was notably diminished in the latter positions. The liver border in the right parasternal line diminished 2 to 4 cm., and the upper heart border was lowered from 8 to 10 mm. when the subject was turned from the position 'face to the west' to the position 'face to the north.' We proved Abrams's studies, which show that the visceral reflexes[2] attain their maximum reaction from electronic energy[3] when the subject faces west."

In my book on "New Concepts in Diagnosis and Treatment" (1916) I have expressed myself as follows:—

> "Tone is an essential attribute of all living organisms, and relaxation is its antithesis. The nerve centres are in a condition of tonic excitation, from which impulses pass to the viscera, maintaining them in a state of tonic stimulation. Every living being transforms energy from the universe. The ideal man is a perfect transformer, and 'Life is a continuous adjustment to the environment' (Spencer). The attraction of man by the sun and the mechanical energy imparted to him by the sun, rotation of the earth, atmospheric pressure, and the electric potential at billions of volts all influence the microcosm by the macrocosm—the world machine."

The writer has shown that the magnetic elements influence visceral tonicity, and that the output of energy varies in relation to the posture of the individual, because the intake of energy is similarly influenced. The organs are in a varying state of tonicity, and the tone may be normal (orthotonic), increased (hypertonic), diminished (hypotonic), or absent (atonic). A relaxed organ will yield a smaller area of dullness than an organ which is in a state of tone.

To accurately reproduce the area occupied by an organ it must possess tone, otherwise topographic percussion is unreliable. It is easy for the physician to show that the borders of the heart will vary according to the posture of the patient, on whom percussion is executed. It will be found that the area of the heart, or, for that matter, any viscus will be greater when the patient faces the geographic west than when he faces the other points of the compass. Note that, when the patient stands in the magnetic meridian supreme tonicity is conferred on the viscera. The latter manœuvre is equivalent to organismal induction from cosmical energy. The writer wishes to emphasise an important fact in the technique of sphygmomanometry (like percussion)—viz., the necessity of taking pressure in a definite position.

Any physician can easily prove that variations, however slight, do occur, and they are most manifest when the patient faces the geographic north during the time pressure is taken. Vital phenomena are dynamic, and organismal action is a process, not a structure. All problems dealing with the physiology of man not in accord with the progress made in physical science are doomed to perish.

In my book the electrophysiologic structure of man is shown with the hands and feet as polar termini. With an apparatus constructed by the writer (electroradiometer) it can be definitely shown that the polarity of the hands and feet of a normal male is positive on the right and negative on the left side. This polarity is reversed in the normal female.

Let the reader forget for a moment that the latter observation is correct and try the following. Percuss the area of the heart with the patient facing the geographical west. Instruct the patient to bring both feet in apposition. Note that the area of the heart is diminished. Instruct the patient to approximate his finger-tips in addition to his feet, and note that in many instances the area of cardiac dullness is practically annihilated. Note, furthermore, that the moment the feet of the patient are approximated, there is a momentary inhibition of the pulse. When the feet and hands are approximated the manœuvre may be likened, in the animal machine to a short circuit in a dynamo which discharges the current within the machine, thus causing its deterioration and minimising its energy output.

---

[2] Handbook of the Medical Sciences, vol. vii.
[3] International Clinics, vol. i., 27th series.

Let percussion of the heart teach us another lesson in the physics of the human organism. The reflexes of Abrams demonstrate that the earth is the negative terminal of nature's energy; that when the electrical tensions between the body and earth become equalised the maximum tonicity is conferred on the viscera. Ground each leg of a patient by means of a wire to a faucet or radiator, and note that the intensity of cardiac dullness is greater after than before grounding. Note also the effect when the patient approximates his feet and hands, and note, furthermore, that the maximum intensity of cardiac dullness is attained when the patient is grounded and stands in the magnetic meridian. The writer has utilised therapeutically the latter data for the purpose of minimising the expenditure of nervous energy in neurasthenia.

GENITO-URINARY TUBERCULOSIS

TREATED WITH MASSIVE DOSES OF TUBERCULIN.

BY ROLF CREASY, M.R.C.S., L.R.C.P. LOND.

IT is common experience that, if we except such radical treatment as the removal of kidney or testicle, the amount of good that we can do to cases of tuberculosis of the genito-urinary system is very small, consisting mainly in the prescribing of sedatives to allay the most distressing symptoms. I bring forward the following short series of cases, which are examples only of a longer list of tabulated instances, in order to show that the administration of tuberculin, in accordance with certain methods, may relieve many patients from wretched suffering, constant pain, and the wearying anxiety of frequent micturition night and day. The relief may amount to cure, and in most of the cases with the relief of symptoms there have come great improvement in general health and marked increase of energy. Many cases which I have treated had been under treatment for varying periods in hospitals, and had found no sustained relief; it is in these patients that reviving hope has been of much assistance towards rapid improvement.

In the light of experience gained from these cases I am sure that many sufferers from genito-urinary tuberculosis, if coming under treatment by tuberculin sufficiently early, and in accordance with a suitable technique, are susceptible of great improvement. But the tuberculin test having proved positive the treatment should be commenced forthwith. There should be no delay until tubercle bacilli are found in the urine; although cases of long standing will apparently respond well to the treatment and can be arrested in their otherwise downward course, prognosis is much improved if the cases are taken early in hand and gradually increasing doses of different preparations of tuberculin are administered over a period of six months to a year. A second or third course may be required after intervals of varying length, and there can be no attempt to lay down exactly a routine treatment for any and every patient.

The technique employed in the appended cases was the following. The injections, which were subcutaneous and usually in the upper arm, were given twice weekly, the weight being recorded and the patients taught to take and record their temperatures four times a day. It will thus be seen that the treatment can be carried out at any distance from the physician's house, the dose being prepared after study of the temperature and weight record, which should be sent twice a week to the physician, when the proper procedure can be indicated to the medical man in private charge of the patient. In this way the treatment need not interfere with the patient's daily occupation; where necessary and in old-standing cases two or three courses of injections can be spread over several years, while the word "cure" should be used concerning no patient until he or she has lost all symptoms and no longer reacts to tuberculin. I append short notes of typical cases at different stages of treatment.

Miss I. P., 23. Six years' history. Onset, frequency and pain. T.B. present in urine. Cystoscoped; isolated tubercles L.U.O., retracted, tuberculous nodules. Micturition half-hourly day and night: severe pain, not relieved by micturition. Tuberculin treatment May 13th to Dec. 12th, 1919: P.T.O., P.T., and Old T. to 1·5 c.cm. Gained 1 st. in weight; much less pain. Frequency, $\frac{\text{day, 6 to 8}}{\text{night, 2 to 4.}}$. Is stronger and better in every way.

Mr. F. B., 50. Twenty years' history of frequency and pain on and off. Hæmaturia on some 12 occasions. T.B. present in urine. Micturition, very little control; wears indiarubber bag. Cystoscoped; incrusted cystitis, several hæmorrhagic ulcers, tuberculous nodules in both epididymes. Tuberculin treatment May 10th to Dec. 3rd, 1919. P.T.O., P.T., and Old T. to 1·5 c.cm. Gained 1 st.; discarded rubber bag. Frequency, $\frac{\text{day, 5 to 6}}{\text{night, 0 to 2}}$, no pain, no hæmaturia.

Mr. F. B., cystoscoped February, 1920. Great improvement; examination not painful; ulcers healed. Maintains his good condition as recorded at end of his course of tuberculin two months ago.

Mr. W. T. S., 37. February, 1918. Right testicle removed for tubercle. Ailing since January, 1919, unable to work since March, 1919; weakness and pain in right kidney. May, 1919: Report from St. Mary's Hospital. "Right kidney removed, pulmonary tubercle on right and left upper lobes." August, 1919: Wasting and debility, frequent micturition. Frequency, $\frac{\text{day, 8 to 9}}{\text{night, 3 to 4}}$. Free purulent discharge from pouting sinus in old nephrotomy incision. Cystoscoped; patches of ulceration, numerous, also isolated tubercles; ℥ vi.; distension, urine dirty. Tuberculin treatment August 5th, 1919, to Jan. 20th, 1920: P.T.O. and P.T. to 0·5 c.cm., course proceeding. Gained over 1 st. in weight; discharge almost ceased. Frequency, $\frac{\text{day, 4 to 5}}{\text{night, 1 to 2.}}$. No chest symptoms.

Mrs. G. M., 35. Three years' history of pain and frequency. Onset, hæmaturia. Cystoscoped; many tubercles on trigone, and on lips of both U.O.'s. L.U.O. large, gaping, œdematous. Pain constant, at times very severe, requiring morphia. Patient wasted, sleepless, tired out. Micturition every half hour, night and day. Tuberculin treatment May 1st to Nov. 18th, 1919: P.T.O., P.T., and Old T. to 1 c.cm. Gained 8 lb., different woman, greatly improved, doing own housework. Occasional attacks of frequency and pain. Usually frequency, $\frac{\text{day, 4 to 5}}{\text{night, 1}}$, and pain very slight; no morphia since May.

Mrs. G. M., Feb. 21st, 1920. Nursed her child through six weeks' severe whooping-cough and bronchopneumonia. Some return of pain and frequency; this again subdued by a few further injections of bacillary emulsion.

Mrs. F. S., 42. Seven years' history, occasional hæmaturia pain varying, often severe. Frequency,

$\frac{\text{day, }\frac{1}{2}\text{ hourly}}{\text{night, 8 to 10}}$. Cystoscoped; ulceration of bladder. T.B. found in urine. Patient weak, tired, and unfit for any work. Tuberculin treatment August 1st, 1919: 0·01 c.cm. P.T.O. to Jan. 13th, 1920; 1·3 c.cm. Old T. Marked general improvement in health. Able to do own housework. Much less pain. No hæmaturia. Better nights. Frequency, $\frac{\text{day, 1 to 1}\frac{1}{2}\text{ hours}}{\text{night, 3 to 4}}$.

Mr. F. C., 30. May, 1919: Constant pain both kidneys and groin for a year; not relieved by removal of two small stones from bladder per urethram six months ago. Now complains constant pain and weakness. Frequency, $\frac{\text{day, every 3 hours}}{\text{night, 1 to 2}}$. Cystoscoped; T.B. around R.U.O. No T.B. found in urine. October, 1919: Slight reaction to 0·001 c.cm. Old T. Marked reaction three days later to 0·003 c.cm. Old T. Started treatment Nov. 1st, 1919: P.T.O. 0·0005 c.cm.; now reached 0·7 c.cm. P.T.O. Pain occasional only, and very slight. Frequency, $\frac{\text{day, 3 or 4}}{\text{night, 0}}$. Feels strong and well; able to work.

Mrs. A. W., 33. August, 1919: Tired, sleepless, and worn out. Practically no control over urine, passing every 10 minutes day and night; great pain and smarting; frequent hæmaturia. Five years ago right kidney was removed for tubercle; two sinuses have persisted since, and are now freely discharging. July, 1916: Cystoscopic examination showed ulcerations of bladder wall; T.B. found in urine. Tuberculin treatment from August 1st to end of December, 1919: P.T.O., P.T., and Old T. to 1·3 c.cm. Wonderful improvement, cheerful and energetic and happy; able to do her housework. Frequency, $\frac{\text{day, every 1 to 1}\frac{1}{2}\text{ hours}}{\text{night, every 1 to 1}\frac{1}{2}\text{ hours}}$. Pain occasional only. The sinuses are nearly healed. Very little discharge. March, 1920: Improvement maintained.

Mr. W. W., 38, husband of A. W., above. August, 1919: Pain in left renal region five years, increased by work. Frequency, $\frac{\text{day, every }\frac{1}{2}\text{ hour}}{\text{night, 0–1}}$. Hæmaturia—once, copious, 18 months ago. Pain, chiefly after micturition, nearly constant. Cystoscoped; no stone, no growth; ? tuberculous nodules. X ray, left kidney nil. T.B. found in urine. Tuberculin treatment, August, 1919, to February, 1920: P.T.O., P.T., and Old T. to 1 c.cm. "Feels better than he has done for ages." Frequency, $\frac{\text{day, 3–4}}{\text{night, 0}}$. No pain; able to do full work.

Miss E. F., 35. A negative case. History: Five years' weakness of bladder. Micturition every half hour by day, once or twice only by night; no pain; no hæmaturia. Tested with tuberculin up to 0·08 c.cm. Old T. (twice). No reaction whatever to any test. Clearly no tuberculosis.

Unsuitable cases for the treatment are found to be the following: 1. Those in which any continued fever be present; such fever is caused by mixed infection, and the patient should be kept in bed till the temperature is normal. 2. Albuminuria; no injections should be given. 3. Epilepsy; in such cases it is as well to decline treatment. Pregnancy is no bar to the treatment.

A common lesson to be drawn from these cases is as follows.

(1) Early cystoscopic examination along with testing by tuberculin should be practised in every suspicious case.

(2) Treatment of all cases, however long standing.

(3) Treatment can be carried out at dispensaries, a great economic gain to the community, patients usually being able to continue their work.

(4) The attendance of patients twice a week is essential for the proper progression of doses.

I am aware that medical men have tried the use of tuberculin in these and analogous cases, and have discontinued it, disappointed at the results. To my mind, the failure has been due in some of of these cases to the method in which tuberculin has been administered. I adopted the technique laid down by Dr. Camac Wilkinson, from whose teaching one of the first lessons which emerges is that neither patient nor physician should be afraid of reactions. The high temperature with unpleasant symptoms for 24 hours leads to no harm, and, in point of fact, is an invariable prelude to improvement. I must express my thanks for the assistance I have received from Dr. Camac Wilkinson, who placed his lengthy experience of tuberculin treatment at my disposal, and to Mr. Canny Ryall, through whose courtesy I was able to carry out the treatment of some 40 cases at All Saints Hospital.

Grafton-street, W.

AN EXPERIMENT ON THE

MODE OF TRANSMISSION OF CERTAIN HUMAN INTESTINAL PROTOZOA.

BY J. C. WATT, *M.C.*, M.B., CH.B. GLASG.,
CAPTAIN, WEST AFRICAN MEDICAL STAFF, ATTACHED KING'S AFRICAN RIFLES.

THE conclusions of Wenyon and O'Connor as a result of that part of their work in Egypt[1] which dealt with the viability under various conditions of cysts of human intestinal protozoa, and of their mode of transmission from one host to another, appeared to negative my own, particularly on the mode of transmission of amœbic dysentery. For reasons subsequently to be stated my experience in West and East Africa led me to believe that amœbic infection was likely to be wind borne, and to lie in the dust of the countries where the disease is prevalent.

Wenyon and O'Connor, however, apparently showed that cysts of various intestinal protozoa, including that of *Entamœba histolytica*, are killed by drying or insolation; they showed that such cysts are frequently ingested by house-flies, and deposited with the fæces of the latter wherever these may alight and feed; the main conclusion being that the ultimate channels of transmission of amœbic dysentery are moist and wet food and water.

The test used by these observers to ascertain the viability of various cysts after drying was the eosin test. Cysts which stained with dilute eosin were considered to be dead, those refusing the stain to be alive. The reliability of this test seemed to me doubtful. It may be true that "a living cell will not stain with dilute eosin, whereas a dead cell will stain at once"; but does a cyst, which is not merely a cell, but also a cell provided with a resistant, although no doubt permeable outer layer or covering, behave in the same way in this respect as will an unprotected tissue cell? It seems possible that a cyst, having lost fluid or having undergone a change in the fluid tension of its contents, but being still viable, may take up a nocuous diffusible substance, such as eosin, on being immersed in a solution of such a substance. Any such interchange, however, of diffusible substances between the interior of a cyst and its surrounding medium must depend on the permeability of the cyst "wall."

---

[1] Human Intestinal Protozoa in the Near East, by Temporary Lieutenant-Colonel C. M. Wenyon, B.Sc., M.B., B S., R.A.M.C., and Temporary Captain F. W. O'Connor, M.R.C.S., L.R.C.P., R.A.M.C.

Now, if it were possible to treat a cyst in such a way as to render its "wall" an impermeable membrane, without damage to its living contents, such a cyst would resist staining. In this connexion one of the findings of Wenyon and O'Connor is significant. They found that exposure of histolytica cysts to various chemical solutions caused them to stain with eosin; but that exposure to 1–100 formalin failed to cause the cysts to stain, "even after four hours ...... though they were very much shrunken and distorted, and gave every appearance of having been killed." It is likely that the resistance to staining in this case was produced by the hardening effect of the formalin on the cyst wall, rendering the latter impermeable, and so precluding the stain from access to the cyst contents.

If this is the true explanation of the phenomenon it seems possible that in conditions resulting in the gradual hardening and drying of such cyst walls—for example, insolation and desiccation—the cyst wall may succeed in preventing damage to the contents of the cyst; in other words, that such cysts may be viable, even although they may present the appearance, from wrinkling of the envelope, of having been killed. This seems the more probable when we consider that the cysts of free-living but closely related creatures remain viable under desiccation. As Wenyon and O'Connor point out, "the Thompsons have shown that the free-living *Amœba limax* produces a cyst which will withstand complete and prolonged desiccation under a tropical sun."

Description of Experiments.

In the experiment I have recently carried out the materials used first were :—

1. Fluid fæces—produced after purgation with mag. sulph.—in which the following organisms were seen :—

(*a*) *Tetramitus* (*Chilomastix*) *mesnili*—numerous.

(*b*) *Trichomonas intestinalis*—not so numerous as the former.

(*c*) A small amœba, sluggishly motile, often extruding several blunt pseudopodia at once, showing a granular endoplasm, the pseudopodia being ectoplasmic, of low refractibility; size equal to, or slightly less than, that of an R.B.C. These I thought might be the *E. nana* of Wenyon and O'Connor, but could not prove this by stained specimens.

(*d*) Cysts, presumed to be of the forms mentioned above, namely: 1. Clear, bottle-shaped, with one or two dark specks, which I diagnosed as *T. mesnili.* 2. Larger, clear, bluntly oval cysts, which I considered might be those of *T. intestinalis.* These mostly exhibited flattening of both sides and ends, and were not unlike lamblia cysts, though smaller and without visible internal structure. 3. Small, spherical, in size about equal to an R.B.C., with coarsely speckled contents, no other internal detail being visible.

2. Stephens's scarlet ink.
3. Rain water.
4. Double strength physiological saline solution.
5. 2 per cent. HCl solution.

The fæcal material was first exposed to the sun for one day, dried in the shade for three succeeding days.

Test A.—Small quantities were then emulsified on slides with rain water, and then, after the lapse of 5, 10, 20, or 30 minutes' interval, were mixed with an equal volume of scarlet ink.

Result.—Most cysts of all three types were seen to be stained.

Test B.—Again replacing the rain water by double physiological saline, the same intervals being allowed before mixing with stain.

Result.—Most cysts of all types stained.

Test C.—(1) The same fæcal material (four days old) not having been exposed to the sun, but after drying on a cover-slip for four hours, was then mixed first with (2) double physiological saline, and immediately also with (3) culture of paramœcium, mostly living and moving actively, (4) scarlet ink.

Result.—One typical tetramitus cyst seen entirely unstained, all other material on the slide—including the paramœcia—being deeply stained, except some motile bacteria.

The reason for making these tests was as follows: I considered the staining of dried but possibly still viable cysts might depend either on (1) their loss of fluid, or (2) their relatively high concentration of diffusible substances. Subsequent experiments, on the same lines, with similar materials, gave equivocal results, most of the cysts staining irrespective of what solutions they were treated with before being mixed with the staining solution. That is to say, having once been dried, even short of the point of complete desiccation, they could not be satisfied with an innocuous solution to the exclusion of the nocuous stain.

The same tests were gone through with lamblia cysts, but these all stained readily and completely after short periods of drying.

One result, however, of these tests was that a few cysts of the type described as those of tetramitus, which had been dried for anything between four and ten days, refused to stain, appearing perfectly colourless.

The original specimen of fæces was then placed aside and re-examined between one month and six weeks later, when a scale of dry powder remained in the flask, which had originally contained between 3 and 4 ounces (fl.) of fæcal material. Emulsified and examined under the oil immersion lens numerous cysts were seen on each slide observed. But although those cysts diagnosed as of *T. mesnili* had been fairly easily found in the fresh material, these were now apparently absent, all cysts seen being curiously alike, and spherical or subspherical, except that a few of the larger oval cysts originally present were still to be found. The majority of cysts seen, however, were about equal in size to an R.B.C.; none showed the lobe or knob characteristic of those of tetramitus. Further, all cysts appeared somewhat crenated, and had lost the glassy appearance they had had when fresh.

Some, however, appeared as shown in Figs. 1 and 2. They appeared as if they might have originally possessed a distinct lobe which had been retracted during desiccation into the main part of the cyst. Indeed, a few gave the appearance shown in Figs. 3 and 4. Later, after immersion in 0·2 per cent. HCl, some of these cysts actually seemed to "fill out," as if resuming the form showing a distinct knob or protuberance.

Test D.—A small quantity of this dried material being now emulsified with sterile water and mixed with an equal volume of scarlet ink was examined under the microscope with surprising results. The large majority of the cysts were entirely unstained. In the repeated examination of many such specimens a cyst was occasionally seen which appeared to be slightly tinged with the stain, but not one was found deeply stained. All the others appeared perfectly clear and colourless against the red or pink background of the slide. After four days vaselined specimens showed the cysts to be still unstained.

Test E.—The same emulsion heated on a slide over a spirit lamp and then stained gave the following result: (1) within half an hour, all cysts slightly tinged; (2) after 24 hours, all cysts stained a deep reddish brown.

Test F.—Some of the fæcal material was emulsified in plain sterile water in small flasks and examined after 24 hours. It was then seen that a large majority of all the cysts had developed into motile amœbulæ, which were, to inspection at least, similar to those I had observed in the fresh fæces; but I concluded that these must be free-living amœbæ, which had either been present in the original fresh stool, or were merely a contamination, having been carried into the fæcal material during the process of drying. I was now doubtful as to the survival of any true tetramitus or trichomonas cysts, but proceeded to a feeding test.

Test G.—A chicken, about 1 month old, apparently healthy, was kept in a cage for five days, its droppings examined while newly passed, both unstained and stained with an equal mixture of 5 per cent. iodine in pot. iod. and Stephens's scarlet ink. No protozoal or other organisms were seen, except bacteria. The chick was then made to swallow, morning and evening, about gr. i.–ii. of the dried fæces originally used—that is, material about two months old. Twenty-four hours after the commencement of the test the chick developed diarrhœa, with mucus in the droppings, but no cellular exudate. The following organisms were then found in the mucus: (*a*) Typical motile trichomonas, numerous. (*b*) Tetramitus, less numerous than the former, moving sluggishly. (*c*) One active amœba, about 6–8 μ in diameter, moving sluggishly, with granular endoplasm, and not very sharply defined ectoplasm; refractility comparatively low. On the second day of infection, besides trichomonas, a few typically motile tetramitus were seen. On the third day of infection the chick still showed diarrhœa in the morning, and the droppings contained large numbers—one or two to each field with a 1/12-inch objective—of tetramitus and trichomonas. Feeding with the fæcal material was stopped, the last dose being given at 6 A.M. on the third day after that on which feeding was commenced. On the evening of the same day, diarrhœa had passed off, and only one or two motionless forms of tetramitus and trichomonas were found. Cysts of the types seen in the original fresh specimen appeared in fair numbers. On the fourth day the chick's droppings were again examined. No protozoa were observed, nor their cysts. The chick was then killed, and the contents of all parts of the intestinal canal examined microscopically. No protozoa were found, but in the material taken from the crop were several of the spherical and subspherical cysts as seen in the dried fæces fed to the chick.

Two other experiments were carried out on chicks. In one, dried fæcal material, which had, when fresh, shown a fair number of tetramitus and trichomonas, with appropriate (?) cysts, was used. This material, after about 18 days' drying, with occasional insolation (Lat. 2°–3° N.), but during very rainy weather, showed all cysts stained when treated with scarlet ink. No protozoal infection was induced in the chick. In the second material, sun-dried, containing *E. histolytica* cysts, failed to infect the chicken, even after 5–6 days' trial. In each case blood and mucus, with a heavy cellular exudate, appeared in the droppings of the chick a few hours after the commencement of feeding with the fæcal material, and the chick in both cases was definitely ill. Immediately, however, on cessation of feeding with the fæcal matter the dysenteric condition cleared up, and the chick entirely recovered.

Conclusions.

Since making these experiments I have had no opportunity of making confirmatory tests; but I feel that, in the case of the first chicken test I have described, there can be little doubt that the chicken was infected by the sun-dried material fed to it, for these reasons: (1) The exact correspondence between the organisms observed in the material fed to the chick and those appearing in the droppings of the chick; (2) the correspondence between the duration of feeding with the test material and the duration of infection; (3) the absence of any intestinal protozoal infection from several other chickens examined, at intervals, over a period of three months, some of these chickens feeding in the hospital compound.

It is possible that the "positive" chicken may have ingested house-flies carrying protozoa or their cysts during the period of the test; but this was not observed and the chick was confined in a cage during the test. No cysts were to be found in the water given to the chick; it was fed with rice. It does not seem possible that the chick could have been so heavily and suddenly infected by the ingestion of, at most, one or two flies.

With regard to the dysentery induced in these chickens I conclude that it was probably entirely due to the irritation of poisonous substances in the fæcal material ingested.

Since making the staining tests described I have noticed that living organisms, such as tetramitus and trichomonas, which entirely refuse to be stained by scarlet ink when they are newly passed in the stool, will, while still showing motion, stain slightly with the same material after having been exposed to room temperature (between 70–80° F. in this case) for a few hours, but without drying other than that due to ordinary evaporation of the fluid fæces containing them. It would appear, therefore, that staining of living organisms—cells—such as these is merely proportionate to the degree of loss of vitality.

I have ventured to make the following suggestions from these tests: (1) That the cysts of *Trichomonas intestinalis* and of *Tetramitus mesnili* may remain viable and capable of reproducing active forms after insolation under a tropical sun. (2) That the staining of certain intestinal protozoal cysts is inversely proportionate to the degree of drying and hardening of the cyst wall. (3) That staining cannot be accepted as a test of the viability of these cysts. (4) That the cyst of *Trichomonas intestinalis* is of a flattened oval shape (flattened as to both sides and ends), slightly larger than the cysts of *T. mesnili*, of clear, faintly spotted appearance when fresh, and exhibiting no internal structure when fresh. I regret I have not been able to use the appropriate stains for these cysts.

It seems likely, therefore, that the infections of *T. intestinalis* and *T. mesnili* may be dust-borne, and I think the experiment I have described is sufficient to warrant a re-examination of the more serious question of the mode of transmission of amœbic dysentery. I have referred to my belief that this disease is dust-borne, and it will be admitted that there are many reasons for supposing this to be the truth. Without going into detail, it is generally remarked that amœbic dysentery is most prevalent in the driest and most dusty countries, and that it is most prevalent in the dry seasons of those countries. Further, I suggest that the onset of rains will cut short prevalent amœbic dysentery. I should like to refer to two presumptive instances of this. First, in the campaign in German East Africa the onset of the rainy season coincided exactly with a very great reduction in the numbers of cases of dysentery amongst the white troops with whom I was serving; and of all cases amongst these I found a very large proportion to be amœbic.

Again, in Gallipoli, it was remarked that the onset of the rain in August seemed to put a stop to the dysentery that had been so prevalent amongst the troops there, and although it has since been questioned that much of the dysentery during the Gallipoli campaign was amœbic, it is at least admitted that that peninsula must be regarded as an endemic centre of amœbiasis. No one familiar with hot dusty countries—and especially with campaigning in these countries—can forget the welcome freedom from dust accompanying the onset of the rains. My inference is that the almost absolute freedom from dust in the rainy season suggests that dust has been the medium of infection where dysentery also ceases with the onset of the rains. It may be argued that the rains also reduce the numbers of flies, but a few hours' sunshine is generally sufficient to cause these to reappear and infest food materials as before.

Note.—On the question of the duration of infections of *T. intestinalis* and *T. mesnili*, one case I know to have lasted for over two years, including a period of four months in England. Cyst formation seems to be irregularly periodic in occurrence.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

INTENSIVE IODINE TREATMENT.

BY TOM BIRD, M.A., M.R.C.S.

CONSULTING ANÆSTHETIST TO GUY'S HOSPITAL.

Dr. Louis Bourdreau published in 1914[1] his experience, of some 14 years' duration, of the intensive treatment of tuberculosis by large and continuous doses of the tincture of iodine of the French Codex. The article is remarkable for three things: his great success as to results in tuberculosis, the large doses that can be given by a gradual increase, and the proof of sincerity in that Dr. Bourdreau did not publish his results until some 14 years after he began the treatment. His colleagues only had knowledge of his work, and he showed rare restraint in delaying publication for so long. He suggests the "intensive treatment of iodine" might be useful in other diseases. The article came under my notice through a letter of Dr. William Ewart, of St. George's Hospital, who resorted to the treatment for his own arthritis with such success that "from being unable to go upstairs one at a time, he could manage three at a time." He took 10 gr. in the day of pure iodine, through the medium of the French tincture (or Indian tincture), neither of which contain any iodide of potassium.

In quite a number of arthritic cases, and in three or four cases of chronic gout, and in those cases called "rheumatic gout," I have had a quite remarkable success, especially as to pain and insomnia. In 1917 I met an old friend, Dr. J. H. Ewart, of Eastbourne, and no relation of the above-mentioned Dr. Ewart, who told me he used the treatment, and "was continually having prescriptions returned by the chemists, who were surprised at the doses." Although he is himself susceptible to iodine, he told me that he could take ʒi of the French tincture for a dose. He wrote:—

> "I tried the treatment. tinct. iodine (French), and began with 10 min., and went on to 30 min. three times a day, and the results were really marvellous; my finger-joints decreased in size in a most wonderful manner. I then went wrong, and began taking 60 min. three times a day, and this ended by giving me a diarrhœa I shall not forget. But to refer to other people. I treated at the All Saints' Convalescent Hospital everybody who complained of chronic rheumatism with tinct. iod. (F.). I don't think the three weeks they were there that I got beyond 30 min. ter die; but the results were really splendid."

With regard to tuberculosis, I have only one case to report. He had been at a sanatorium, and was apparently cured; but in a comparatively short time began to fail, and at last came hæmorrhage. I had already advised him to try iodine as a prophylactic. When the hæmorrhage came he was alarmed and began to take iodine. Some two months after I met him by accident and was surprised at his healthy appearance; he was, he said, quite well and had increased 10 lb. in weight. One swallow does not make a summer, but a swallow is a happy omen when it comes.

Some people are susceptible to iodine, as is my friend Dr. Ewart, of Eastbourne; yet he arrived at ʒi. doses. I generally order 1 gr. after meals three times a day the first week, 2 gr. the second week, 3 gr. the third week. For arthritis I seldom give more. Beyond slight catarrh of the nasal mucous membrane, of the possibility of which I warn patients, I hear of no inconvenience, certainly no iodism. If the treatment has been left off it is better to begin again with small doses, as diarrhœa may follow a large dose. When pain and swelling have been relieved my custom is gradually to discontinue the medicine. It is unfortunate that the article in the *Journal de Médecine* is out of print, and apparently unobtainable, as some of the details recorded are interesting and illuminating.

The notable absence of iodism following the use of the French tincture suggests that it might be used instead of iodide of potassium.

Conduit-street, W.

A CASE OF OSTEITIS FIBROSA.

BY NORMAN C. LAKE, M.D. LOND., F.R.C.S. ENG.,

SURGEON, QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY-ROAD, E.;

AND

NORAH H. SCHUSTER, M.B. VICT.,

HOUSE SURGEON, QUEEN'S HOSPITAL FOR CHILDREN.

THE chief point of interest in this case was that, although the X ray photograph so closely resembled that of Mr. E. G. Slesinger's case which appeared in THE LANCET of Nov. 15th, 1919, and very strongly suggested cyst formation, both the operation and subsequent microscopy showed the complete absence of cysts.

The patient, a girl aged 7 years, attended the Queen's Hospital for Children in March, 1916, with a history of a fall three years previously and subsequent limping. There was no shortening of the limb or tenderness, and a bony swelling was felt over the upper end of the femur. The X ray showed a coxa vara with questionable signs of old tuberculous disease or periostitis.

---

Skiagrams illustrating (1) Mr. Norman Lake's case of Osteitis Fibrosa in a Girl aged 7; and (2) Mr. E. G. Slesinger's case of Osteitis Fibrosa of Upper End of Femur in a Woman aged 25.

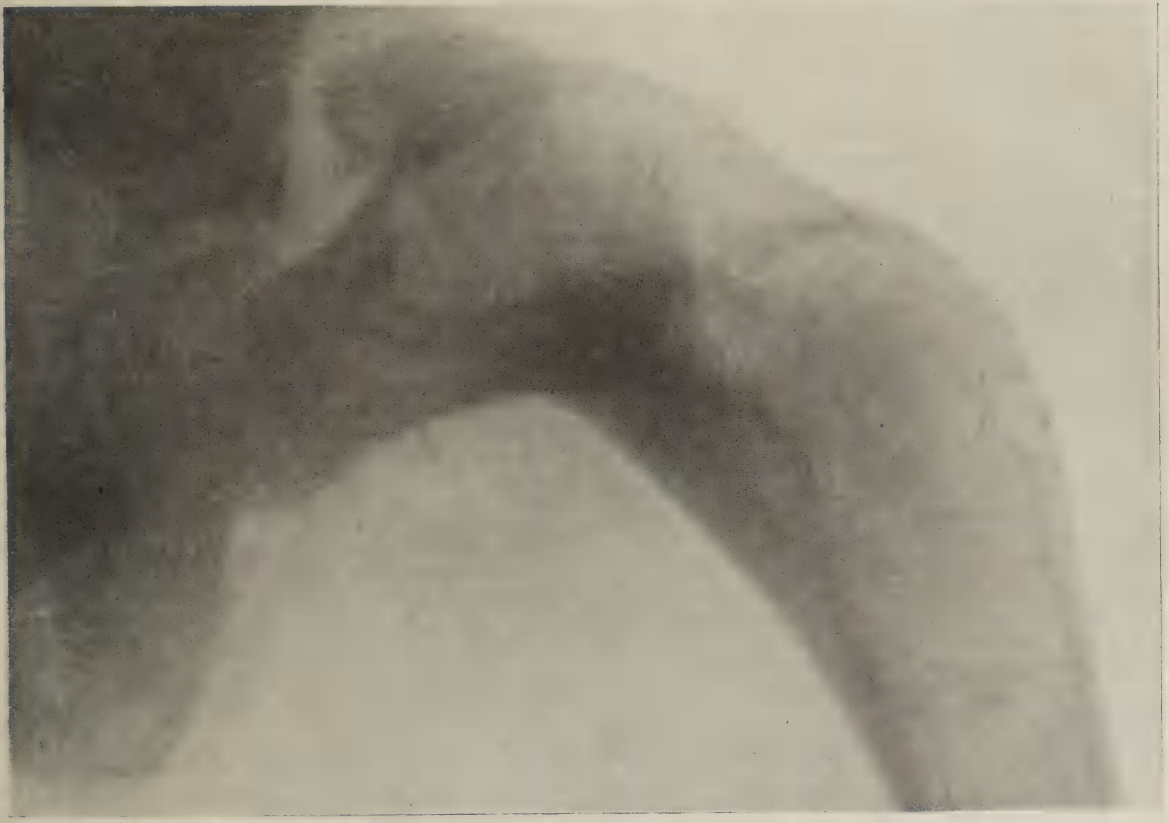

FIG. 1.—Mr. Lake's case.

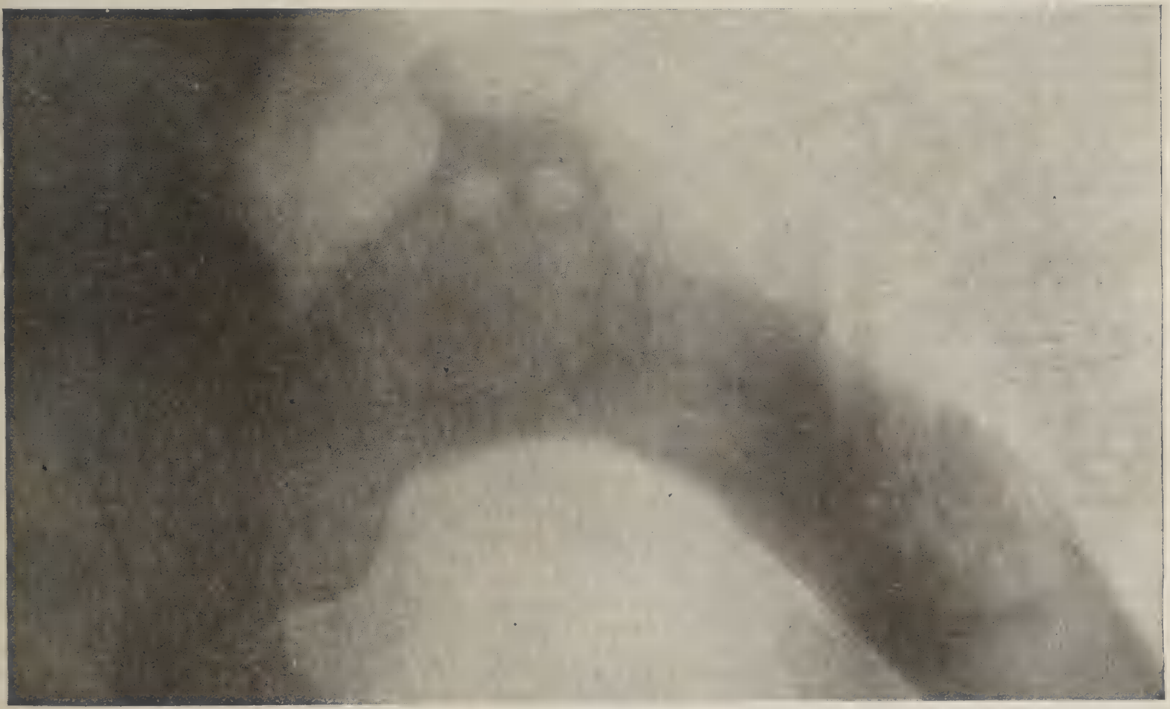

FIG. 2.—Mr. Slesinger's case (reproduced from THE LANCET, Nov. 15th, 1919, p. 868).

The case appears to have been left until a year later, when the X ray report says "an old greenstick fracture at about the level of the lesser trochanter, with curvature of the upper part of the shaft and some lessened obliquity of her neck."

In August, 1917, a sub-trochanteric osteotomy was performed, and at the operation the bone was noted to be thickened antero-posteriorly, and to be of a soft spongy consistency, not easily broken. The limb was immobilised in plaster for four months, and later treated with massage until the patient returned to hospital two years later complaining of pain in the hip. A large bony swelling was present over the outer surface of the femur. The X ray now showed expansion and rarefaction of the upper third of the femur.

One of us (N. C. L.) then removed a piece for examination, which was reported by Dr. W. C. Topley, of Charing Cross Hospital, to consist of "a loose fibrous matrix in which are embedded irregular islets and trabeculæ of imperfectly formed cartilage. There is no cyst formation, calcification is almost absent, but several of the cartilaginous areas show the other changes connected with commencing ossification. No true bone marrow is present." The whole of the diseased spongy tissue was then removed, first cutting through a thin shell of normal bone, and then curetting along the great trochanter into the neck. The periosteum was left, and a thin shaft of normal bone along the inner aspect of the femur. The wound healed without interruption, and subsequent X rays showed growth of callus, but no signs of a return of the tumour.

The history of this case leads to the conclusion that the osteitis fibrosa was secondary to a traumatic coxa vara.

Note.—Since the above was submitted for publication, one of us (N. C. L.) has had a somewhat similar case at Charing Cross Hospital. The patient, a girl of 19, had a spontaneous fracture of the neck of the left femur three weeks previous to admission. A radiogram showed the typical appearance of the bone surrounding the fracture. There was an indurated gland in the groin which on section, however, proved to be chronically inflammatory. Microscopy of the diseased tissue removed showed it to be of exactly the same structure as the first case. With regard to this case the following points are of interest: absence of mechanical trauma, although there is reason to believe from her previous history of pain that she probably had some infective trauma of mild degree; negative history of syphilis and negative Wassermann; absence of Bence Jones's proteid from the urine, and no cyst formation despite the definite indications of the radiogram.

A NOTE ON THE

POSTERIOR NERVE ROOTS OF THE SPINAL CORD:

THEIR STIMULATION IN THE LIVING SUBJECT AND DEMONSTRATION OF DECUSSATION OF THE NERVE FIBRES.

BY E. P. CUMBERBATCH, M.B. OXON., M.R.C.P. LOND.,

MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, ETC.

WHILST investigating the electrical excitability and conductivity of the nerve trunks of the lower limbs for purpose of diagnosis I have made attempts to stimulate their roots of origin at their exit from the vertebral foramina or in the neural canal. Very strong currents are necessary for this purpose, because the nerve roots lie some distance below the surface. The first attempts were unsuccessful, and no muscle in the lower limbs could be made to contract even when the current had reached the maximum strength which could be tolerated. The faradic and galvanic currents were first used. The galvanic current causes much pain, and the ordinary tetanising faradic current, though less painful, gives a very disagreeable sensation when its strength is much increased. If, however, the primary current is interrupted much less frequently, say once a second, the single shocks caused by the induced current in the secondary coil at break can be tolerated with little or no discomfort. The primary current can then be further increased (or the secondary coil pushed farther over the primary) and a much stronger stimulus can be applied and borne without pain. The coil which I have used for this purpose is the Tripier coil. This is provided with a special see-saw interrupter which can break the primary current any number of times, from 1 to 60 per second. A coil, of English make, known as the "Physio" coil[1] is fitted with a similar interrupter.

If an electrode consisting of a padded metal disc, $\frac{1}{4}$ inch in diameter, is placed on the skin over the lumbar vertebræ, with an indifferent electrode on the abdomen, and the interrupter regulated so as to break the primary current once a second, the secondary coil can be gradually moved over the primary till contractions of the lower limb muscles occur. The region to which the active electrode must be applied lies over the second, third, and fourth lumbar vertebræ, $\frac{1}{2}$ inch from the middle line. The skin must be well moistened, and the electrode pressed as close to the vertebræ as possible.

In the first patient on whom I tried this form of stimulus I noted that the muscles of the lower limb *on the opposite side* contracted. I then applied a similar stimulus to three normal subjects, one male and two female. Similar results were noted. If the current was much increased the muscles of both lower limbs contracted, but those on the opposite side contracted more strongly. When the current was reduced contraction was noted only on the opposite side. In one of the subjects a particularly strong contraction of the opposite quadriceps was noted, even when that of the same side was quiescent. It was well demonstrated when the subject lay face down with the knees flexed to a right angle. Each time the primary current was interrupted the quadriceps on the opposite side gave a sudden tug, and if the ankle was held by the operator the effort of the muscle to extend the knee was felt, and no pull was felt on the same side. The contraction of the opposite quadriceps occurred when the active electrode was placed anywhere on the region mentioned on the second, third, and fourth vertebræ.

In this experiment the contraction is due, in all probability, to stimulation of the *posterior* nerve roots in the cauda equina. If it were due to stimulation of the *anterior* roots, contraction would have occurred on the same side, or more strongly on the same side than on the opposite, and the groups of muscles contracting would have been smaller as the electrode was placed successively on the second, third, and fourth lumbar vertebræ, thereby stimulating successively smaller numbers of nerve roots.

Another observation made during these experiments was that reversal of the direction of the induced current (obtained by reversing the primary current) was followed by little or no contraction on either side.

These experiments appear to demonstrate the decussation of the afferent (sensory) nerve fibres after entering the cord.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

EARLY MANIFESTATIONS OF SCURVY.

A MEETING of this section was held on Feb. 24th, Dr. A. F. VOELCKER, the President, being in the chair.

Mr. RANSOM PICKARD and Dr. G. W. LLOYD read a paper entitled "Early Manifestations of Scurvy." Two groups of cases were described having the same symptoms, but investigated from a somewhat different standpoint. Another group, bringing the total number of cases to 32, was examined, presenting the same symptoms, but was not referred to in detail. The manner in which the first group was discovered was of interest. In August, 1915, in a divisional rest station in France, there was a large number of cases in which the symptoms complained of were pains in the joints and muscles. In an investigation of these a proportion were found to be anæmic and to have an affection of the gums, either pyorrhœa, bleeding, or loose teeth. It was at first assumed that the pains and anæmia were septic in origin, the cause being the diseased gums. Two patients were then noticed to have each a subcutaneous hæmorrhage. Upon this scurvy was thought to be a possible explanation, and tests were devised to detect night-blindness. By these it was obvious that 9 of the 12 cases in the first group had a moderate degree of night-blindness though none of them had complained or were aware of it. The second group was chosen in a different manner, ten men being picked out who appeared to be the most anæmic. Their hæmoglobin content was then estimated. One suffering from whitlow and another from tertiary syphilis were excluded; neither of these had night-blindness. The remaining eight were then examined as to pain, affections of the gums, and night-blindness; they were found to have some or all of the symptoms. Three cases in the first group had rashes, consisting of a few purpuric spots each around a hair follicle on the front of the thighs and occasionally on the legs. They would fade and one or two fresh spots appear. They were about 2 mm. in diameter. Subcutaneous hæmorrhages consisting of indurations covered by discoloured skin, as in a bruise, occurred on the buttocks, outer part of thighs, and upper arms. In two cases after becoming absorbed they reappeared at the same sites, their position being, no doubt, due to pressure by lying on the ground. Many had the grey necrosis of epithelium of the mucous membrane at the dental edge of the gums characteristic of ulcerative stomatitis, which at about this time appeared in the army. The contention was that anæmia, pains in the joints and muscles, ecchymoses, swollen gums with suppuration, bleeding or loose teeth, and night-blindness formed together the picture of scurvy in its slighter degrees, and were in miniature the same symptoms that exist in the severe cases usually designated "scurvy."

The methods which had been devised for detecting night-blindness were then detailed. A group of controls was taken from among other patients at haphazard, except that they had no pains, gum affections, or anæmia. None of the controls had night-blindness, whilst 16 out of 20 men with the foregoing symptoms were so affected. Charts were constructed to determine whether there was any correlation between the symptoms which could be mathematically expressed, such as percentage of hæmoglobin, the vision by night or candle-light, and the field of vision, or between these and the months of service oversea, but there was no approach to a constant relationship.

Effects of Fresh Food on Scurvy.

In August, 1915, the troops of the division from which the cases were drawn were in the trenches from four to six days at a spell, during which time they had no fresh meat or vegetables. Out of the trenches they had an ample supply of these. Thus they were intermittently short of vitamines, and hence the cases were of slight degree, few in number, and of erratic incidence, only very susceptible individuals being affected. No cases occurred in those above the rank of corporal, presumably because they had a greater variety of food. All but one of the 32 cases occurred in infantry battalions—i.e., in units which had spells of trench duty. In the autumn of 1915 the cases practically ceased, owing, probably, to the fact that the men were able to acquire fruit and vegetables locally. Shortly afterwards fresh meat and vegetables were provided for men in the trenches. In the first half of 1916 a few isolated cases were seen; after that there were none.

The practical bearing of these cases upon civilian work was obvious. Where there was a real lack of food in big cities there was a possibility of finding mild cases of scurvy, and it was claimed that the group of symptoms given would lead to a correct diagnosis. Such cases were particularly likely to occur in women whose work is sedentary and done at home, and whose food is often scanty.

SOME DEFICIENCY DISEASES AND LEPROSY.

Mr. A. STAYT DUTTON read a paper on Some Deficiency Diseases and Leprosy. Having spoken of the connexion between beri-beri and scurvy and deficiency in the diet, he considered leprosy, and referred to Sir Jonathan Hutchinson's investigations. This observer appeared to have been convinced that the food-supply has a considerable effect in its production and noted that it never developed in the United States, with the exception of parts of California, attributing this to the circumstance that it is almost the only country where colonisation took place without an initial stage of considerable hardship, and that a good variety in foods was practically always available. Though leprosy was considered to be due to the *Bacillus lepræ* it was remarkable how closely the nervous symptoms of beri-beri resembled those of lepra anæsthetica. The numbness, anæsthesia, loss of power in the legs, arms, and hands, as well as other symptoms, were very similar, and might in both diseases result in muscular atrophy with foot-drop and wrist-drop. Each was also particularly prevalent in the Far East. Lepra anæsthetica could occur without association with lepra tuberculosa, and be present for a considerable time before the latter eventually made its appearance, and Hutchinson had said that the tuberculous variety never occurred before the anæsthetic kind was in evidence. This appeared to support the food theory. The speaker did not suggest that leprosy was caused by the taking in of bacilli in fish, but there seemed to be the likelihood that when the food-supply mainly consisted of it a deficiency in diet occurred. Salting modified the flavour of the fish, and, according to Liebig, one-third of the nutritive value of meat was lost during the process, and some such change might reasonably be expected in the case of fish. Hutchinson showed that in Iceland and Norway, where leprosy is common, it prevailed more generally on the sea-coast or near lakes and rivers where fish is consumed. It was likely that leprosy might eventually be recognised as partly a deficiency disease, sometimes owing to a predisposition caused by a diet mainly composed of fish, and sometimes to a dietary deficient in various necessary elements. The theory of contagion was not generally accepted, though the case of Father Damien appeared to favour it.

Having considered the possible means of infection by the *Bacillus lepræ*, he said that the discovery of this bacillus had at first led Hutchinson to believe that the ætiology required no further investigation, but later he became aware that this was not the case. It now seemed possible to arrive at conclusions more likely to be accepted—namely, that leprosy is largely predisposed to by defective feeding and by defective personal hygiene, sanitation, housing, and environment, the bacilli then gaining access to the body, with the possible subsequent addition of the whole chain of tuberculous manifestations. The question of prevention seemed to resolve itself into the need of conforming to customs and habits found efficient in England and elsewhere, particularly in regard to food and hygiene, with, in addition, the isolation of those infected with the bacillus.

SECTION OF OTOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on Feb. 20th, Dr. ALBERT A. GRAY (Glasgow) occupying the chair.

Cupping of Auditory Meatus.

Mr. RICHARD LAKE showed a patient who presented Congenital Cupping of the External Auditory Meatus, with Keratosis. The depression occupied most of the external two-thirds of the meatus, with the exception of the orifice. The patient's mother also had been under Mr. Lake's care for the results of a similar condition. The meatus was first dilated by a tube and then ether was instilled. There had been marked improvement.

Purulent Meningitis.

Mr. J. F. O'MALLEY and Dr. P. WATSON-WILLIAMS showed cases of Purulent Meningitis, in which recovery ensued. Mr. O'Malley's patient collapsed in the street, but the practitioner did not regard the condition as serious and prescribed "ear drops." At the end of the second week pain commenced in the left ear, with attacks of vomiting, followed by deafness. Mr. O'Malley found a large perforation in the right tympanic membrane and some pus in the middle-ear cavity. In the left ear there was profuse suppuration from the middle ear, with total loss of membrane and much granulation tissue posteriorly in the tympanum. There was intense headache, and the neck was held rigid on account of pain caused by attempted flexion. Kernig's sign was absent, and his temperature was 103° F. Lumbar puncture was done, 25 c.cm. of slightly opalescent fluid being drawn off; it was not under great pressure. There were 45 per cent. of polymorphs, 55 per cent. mononuclears, Gram-positive diplococci and Gram-negative bacilli, with marked polar staining. A mastoid operation was carried out and definite sepsis found. A second lumbar puncture was done and there was marked improvement. The recovery was slow but uninterrupted.

Dr. WATSON-WILLIAMS'S case was that of a man, aged 37, who had had running from the left ear since boyhood. At times there was much pain in the ear. He had vertigo, falling to the left, objects viewed appearing to swing to the left; spontaneous nystagmus to the right. There was pain at the back of the neck, with retraction of the head. Lumbar puncture was done and 40 c.cm. of the fluid removed. It was under increased pressure, and the patient's temperature was 100° F. A radical mastoid operation and labyrinthectomy were carried out. The external semicircular canal was opened up, also the ampulla and cochlea. Ten days after the operation the patient again had headache and head retraction. Cerebro-spinal fluid was again removed, and it was very turbid and under pressure. Collosol argentum, 1 c.cm., was intrathecally injected. There were 16,800 leucocytes per c.cm., 90 per cent. polymorphs, diplococci, and *Streptococcus brevis*. Further lumbar punctures and collosal injections were carried out, and gradual convalescence followed. He now walks without experiencing vertigo. There is facial paresis, but no reaction of degeneration.—Mr. E. D. DAVIS, Mr. G. W. DAWSON, Dr. DAN MCKENZIE, Mr. SOMERVILLE HASTINGS, Mr. ARTHUR CHEATLE, Mr. W. STUART-LOW, Mr. G. J. JENKINS, Mr. SYDNEY SCOTT, and Dr. GRAY discussed the cases, and Mr. O'MALLEY and Mr. E. WATSON-WILLIAMS (who exhibited the case for his father) both replied. The latter said cocci were found in the fluid before the operation; and it was difficult to think the labyrinth was infected after the operation, and by the eighth day the wound had granulated and had been dressed with silver-soaked gauze.

Menière's Syndrome.

Mr. L. COLLEDGE showed a man, aged 42, who, five years ago, suffered for 12 months from repeated attacks of giddiness. He recovered from these after an operation on the nose. For two months he had now had repeated attacks of vertigo, in which he fell forwards; he also had deafness and tinnitus of the left ear. The tinnitus was temporarily relieved by catheterisation, but not the deafness. Wassermann reaction was positive, and much improvement had followed inunctions with mercury.

Mr. STUART-LOW recommended ½ g. doses of quinine three times a day for the tinnitus, and the stoppage of tea and tobacco. They should rest in bed for a time.

Dr. W. H. KELSON related a case of his own, five years ago, in which giddiness prevented the man following his occupation. Removal of the wall of the external semicircular canal produced such an improvement that the man could resume his work. He was well two years ago.

Dr. GRAY agreed as to the help derived by the patient resting in bed. He had not found drugs of much use, except iodide of potassium, and even that, if given in sufficient quantity to stop the vertigo, caused so much depression as to make the life of the patient a misery. Deprivation of tea and tobacco he agreed with; any poison was bad for the condition.

Malignant Ear Disease.

Mr. SYDNEY SCOTT showed three Malignant Ear cases, and discussed his operative procedure in each.

Dr. DAN MCKENZIE showed a case of Cyst of the Tympanic Membrane.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

AT a meeting of this section of the Royal Society of Medicine held on Feb. 27th, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair, the subject of the Influence of the Accessory Food Factors in Infant Feeding was ably introduced by Dr. E. MELLANBY. Professor D. NOEL PATON followed with a well-considered plea for the investigation of rickets from the clinical and experimental side, and the discussion, which will later be dealt with at length, was continued by Dr. ROBERT HUTCHISON, Dr. C. J. MARTIN, Dr. E. A. BARTON, Dr. ERIC PRITCHARD, and others.

MEDICAL SOCIETY OF LONDON.

SURGICAL TREATMENT OF THE LATER STAGES OF GUNSHOT INJURIES OF THE CHEST AND OF EMPYEMA.

A MEETING of this society was held on Feb. 23rd, Mr. V. WARREN LOW, the President, being in the chair, when Sir CHARTERS J. SYMONDS read a paper with the above title. He said that as the result of war injuries there remained a number of open pleural cavities requiring surgical treatment; these had followed either the drainage of a septic hæmothorax or an open wound. The same was true of some of the empyemas which had not infrequently occurred after the pneumonia complicating influenza. He gave an account of the results of some recent attempts to close these old suppurating pleural cavities. The main object of the investigation was to inquire how far the lung could be released by removal of the adventitious layer covering it—i.e., by decortication. The number of patients submitted to operation was 19, and 24 operations had been performed, counting only those made after the primary drainage. In 14 one operation was sufficient to secure practical recovery; 2 required a further operation for removal of the second rib; 1 had three operations, all comparatively small. The remaining 2 were still under treatment; one had had two operations and the other one; both promised recovery. Of the 19, 1 had had four operations and another six before coming under treatment. Of the cases dealt with, 7 had been the result of ordinary empyema, 1 was a sterile hæmothorax, 6 were examples of septic hæmothorax operated upon soon after the wound, and the remaining 5 had open wounds of the chest. The operations consisted of resection of the ribs in some to obtain access only, in others to bring about collapse of the chest wall as well; of decortication of the lung and removal of the thickened pleura from the thoracic wall; lastly, of the transplantation of flaps of muscle into the cavity. In most of the operations an attempt was made to detach the adventitious layer covering in and binding down the lung; in others the pleura was simply scored. Access was obtained by removal of the fourth and fifth ribs from the front. The thickened pleura was removed from the thoracic wall in those cases where muscle flaps were used. In most of the cases, while the thoracotomy served to bring about closure by the falling in of the thoracic wall, he considered that some expansion did take place when the lung was found to be airless, and that when it had receded, as measured by the probe, some expansion took place later on.

Conditions met with at Operation.

At the operation four conditions were met with. 1. The adventitious layer stripped off easily, exposing an unbroken and glistening pleura; the lung filled the cavity and recovery was rapid. 2. The adventitious layer could be removed and the lung freed, but expansion was not immediately permanent; in this form the air vesicles were torn and air escaped in many places; expansion varied in extent and did not reach his expectations, though, on the whole, the procedure was full of promise. 3. Detachment of the layer was possible, but not without including some of the pleura; there resulted a dark red, spongy, airless lung tissue which rose sponge-like into the cavity and gave promise of some permanence, but so far as could be judged no part became aerated and useful. 4. This type was found in most of the cases of old gunshot wounds and in the empyemata long under drainage; the adventitious layer was part and parcel of the visceral pleura, and the two could not be separated; the lung was dark, firm, airless, and smooth on section, when torn no air escaped, and there was little bleeding; the adventitious layer was thinner, as though it had undergone organisation.

In estimating the size of the cavity the best information was gained by a long curved probe or metal sound. With this the most complete exploration could be made, the swing of the antero-posterior curve giving the lateral dimensions. The end thrust against the chest wall could be appreciated by the hand outside. The X ray screen came next in value both with and without bismuth. In addition to exhibiting the cavity, evidence could be obtained as to the condition of the lung and the movements of the diaphragm—the latter a most important point in prognosis. Auscultation and percussion completely failed to demonstrate the dimensions of the pleural space.

Methods of Using Bismuth.

Two methods of using bismuth were employed, first by filling the cavity, and second by introducing a rubber tube containing bismuth. In the first Dr. R. Heath, of Weymouth, directs that the patient should be placed so that the orifice is uppermost and the bismuth (30 per cent. in paroleine) injected through a rubber tube which reaches the deepest part of the cavity. The tube should be small so that the air can escape. The second, a convenient method, was to fill a thin-walled rubber tube 2 to 3 feet long with bismuth or barium, tie both ends and introduce it into the cavity; in this way a fairly accurate outline of the cavity could be demonstrated. Neither method, however, gave the lateral extent of the cavity unless a stereoscopic picture were made.

The Operations Described.

Having ascertained the position and dimensions of the cavity the fourth and fifth ribs were removed from the front. In recent cases the ribs above and below were retracted, which gave sufficient room to decorticate the whole lung. It was necessary to remove the thickened pleura at the same time. If a little more room was required division of the rib above added materially to the space. When the ribs were approximated, as was found in most of the cases, two ribs would require removal. The adventitious layer could, in a recent case, be broken through with the fingers in front and behind and the lung set free. Then the lung itself was exposed, the adventitious layer coming away and leaving a normal pleura. In older cases the facility with which the adventitious layer could be removed varied greatly. In the fourth variety it could not be detached, and then the pulmonary pleura could be curetted or divided into squares or cut in vertical lines. In addition to removal of ribs to permit collapse of the chest wall, flaps of muscle had been introduced, a procedure especially advisable when the apex was affected, for it was important to leave the first rib, and dangerous to remove it. The cases related showed that by muscle transplantation the apex had been closed. When muscle transplantation was done the thick parietal pleura had been removed except at the apex. In completing the operation the anterior wound had been closed, and a drain left in the old sinus in all the cases with extensive cavity. In some, where the cavity had existed chiefly in the upper part with a small tract leading to the opening the drain had been introduced where the cavity was largest. An important question arose as to whether, after the lung had been freed and filled the pleural cavity it would have been wiser to excise the old drainage opening and close the cavity. In small cavities resulting from open wounds the thick hard pulmonary boundary was scar tissue and not a layer of adventitious material, and should not be disturbed.

Risks from Shock and Septic Infection.

The two risks in these operations were shock and septic infection of the recently divided structures. Since the use of bismuth injections had been resorted to before operation the danger of infection had practically disappeared. In only one of the 24 operations was there any anxiety. The temperature seldom reached 101° F. The men arrived, as a rule, with septic pus and small openings. When necessary the opening was enlarged without removal of bone, and the cavity irrigated with saline and peroxide, and then filled with 30 per cent. bismuth in paroleine daily for three to seven days. At the operation all exposed surfaces were rubbed over with this preparation. Shock had never been of sufficient importance to demand treatment, nor had hæmorrhage given cause for anxiety. The anæsthetic employed had been warm ether.

After-treatment.

After-treatment was a matter of prime importance. Captain H. K. V. Soltau, who carried this out, had varied the reagents. He used the Carrel-Dakin method when the cavity became septic or the discharge abundant, after a time substituting permanganate in some cases. Chloramine-T paste was also used, but, on the whole, proved troublesome, and was difficult to remove when suppuration continued. Peroxide was the customary reagent for irrigation; when a bronchial fistula existed oxygen was employed. Another feature of his practice was early exercise, the patient being allowed up as soon as possible, sent out when the weather was suitable, and encouraged to walk about and do work in the wards. Finally, several wounds were closed by excising the sinus and suturing the muscle and skin. An important feature in the after-treatment was the use of elastic in the bandage in the form of an elastic lace, which obviated restriction of chest expansion and limitation of breathing.

Empyema.

Speaking of empyemata, he said that it would be agreed that the chief cause of delay and failure to recover after empyema operations was faulty drainage. There seemed to be an impression in the minds of a good many that a large tube kept up discharge and prevented closure. He then narrated instances where recovery had been delayed by too early removal of the tube or employment of one too small. Prolongation of septic infection, as shown by continued pyrexia or the abundance of pus, and recurrent pyrexia associated with increase of suppuration were very important causes of delay. He was convinced that these drawbacks could be prevented and removed by irrigation of the pleura at the operation and removal of the fibrinous material. He did not think that there was any danger in irrigation when carried out in the recumbent position. He advocated early operation when an empyema failed to heal. The time had come to interfere and release the lung when a large cavity was demonstrable by a sound or by bismuth at the end of about four weeks. If periods of pyrexia had occurred the operation was then all the more necessary.

Discussion.

Mr. H. E. RAWLENCE, who had collaborated with Sir Charters Symonds in the treatment of these cases, said that the method contrasted very favourably with the older type of operation. When using bismuth the carbonate or the salicylate were easier to introduce than the subnitrate. Anæsthesia had been by oxygen bubbled through warm ether, employing one of the special forms of apparatus used, and preceded by morphia and atropine. Patients seriously ill had expressed themselves as relieved directly after the operation. There had been a remarkable freedom from secondary hæmorrhage.

Sir CHARLES BALLANCE advocated the removal of the hæmothorax early in cases in which this occurred in connexion with gunshot wounds, for if left a foul empyema resulted. Before the war he had been disappointed in the treatment of chronic empyema by the operations of Estlander and Schede. From the point of view of obtaining expansion of the lung and recovery of the patient he favoured the principle of no drainage and reliance on aspiration.

Sir GORDON WATSON said that he had found that in recently wounded men if a hole were left in the chest the mortality was high, and he had endeavoured to get such a hole sewn up even at the advanced dressing station. Of 3000 cases of gunshot wounds of the chest met with during the Paschendaele fighting the mortality was 40 per cent. with an open "sucking" pneumothorax, 40 per cent. from septic pneumothorax which had been drained, and under 30 per cent. when the pneumothorax had been washed out and sewn up. On the Italian front the mortality was much better. Four or five cases of empyema in which he had sponged out the pleura with 1 in 1000 flavine and sewn up the wound completely, and thereafter aspirated daily, did extremely well.

Mr. J. E. H. ROBERTS said that provided that all the solid adventitious material were removed from the chest cases did best if the chest were closed and aspirated. It was a very ordinary occurrence for bacterial infection to disappear when this was done. Possibly the bismuth preparation would save time, and be better than the Carrel-Dakin solution which he had used, but he thought that the solution had a softening effect on fibrous tissue. It was advisable in empyema when the patient's condition permitted to clear out the fibrinous deposit, both on the visceral and parietal pleura. With regard to the anæsthetic the best results were obtained with gas and oxygen, which he combined with a local anæsthetic, believing that it increased the patient's comfort after the recovery of consciousness.

Dr. P. MONTAGUE SMITH read a paper entitled,

THE AFTER-RESULTS OF CERTAIN SURGICAL OPERATIONS.

Speaking of tonsils and adenoids, he detailed the secondary effects produced by their presence. Amongst them he mentioned rheumatism, which, in his opinion, gained an entry through the tonsils. He had observed that epistaxis in childhood appeared to be indicative of rheumatic infection, and others had watched the frequent irregular rises in temperature in children with chorea, and, ascribing this to tonsillar infection, had found that removal of the tonsils benefited the chorea. It was of great importance to remove the tonsils and adenoids before the secondary effects were manifest, and at a time when, by regular inspection of children, it could be ascertained that the throat and nose were *becoming* affected. This operation, intrinsically simple in its character, should be more widely practised and was one that every general practitioner should be able to perform. He saw no advantage in the radical operation of enucleation, since complete removal could be obtained by using the Mackenzie guillotine reversed, and his experience over many years had shown that if a small piece of tonsil were left it did not impair the success of the operation. Tonsils partly removed might, with the growth of the child, assume larger proportions, and, if necessary, be again dealt with. Adenoids undoubtedly might grow again, but seldom to an extent sufficient to require operative treatment, and, if it should appear necessary, a further curettage was a very simple matter. The necessary after-treatment was breathing exercises. The parents should always be instructed as to the great importance of these to institute correct methods of breathing, otherwise the fruits of the operation would be likely to be lost. The after-results were excellent, and, in fact, removal of tonsils and adenoids was one of the most beneficent operations that had ever been devised.

The second preventive operation to which he referred was circumcision. This was commonly inefficiently performed, the frequent fault being that not enough prepuce was removed. For subcutaneous nævus he could not resist the conclusion that the ideal operation, where possible, was excision. The operator should keep wide of the growth, and never endeavour to stop bleeding until it had been removed. In his experience the results of tuberculin in the treatment of tuberculous dactylitis were excellent. For tuberculous glands of the neck he disapproved of set operations and said that treatment on sanatorium lines, dealing with breaking down foci as they occurred, was likely to be successful in the majority of cases. He had found that the treatment of tuberculous peritonitis by opening the abdomen and, if thought advisable, by flushing the peritoneal cavity with saline had been attended, in many cases, with excellent results. After speaking of empyema, hæmorrhoids, and cholecystectomy, he referred to gastro-enterostomy, and regarded it, on the whole, as a remarkably successful operation, though some cases were very disappointing.

Prostatectomy.

His experience with prostatectomy had not been good. From cases in which this had been performed he had learnt several lessons. First, the extreme importance of a most careful and systematic preparation of the patients before operation: (1) by the gradual deflation of the bladder step by step, otherwise there was very considerable risk of hæmorrhage from the release of pressure on the kidney; (2) by the maintenance of the bladder in a practically empty condition for at least a fortnight, if possible, before any operation was undertaken; (3) by a constant endeavour to keep the urine acid by large doses of acid phosphate of soda before operation. Secondly, he had learnt that under any circumstances prostatectomy must be a very grave operation. Thirdly, he understood that bacteriological examination of the urine with these cases *before* catheterisation disclosed a single infection, whichever the organism might be. Fourthly, he learnt that the removal of the prostate did not mean, at any rate invariably, that the patient would be able to empty his bladder correctly. He concluded by saying that he had endeavoured to give a few impressions gathered by one in many years' experience of practice as a general practitioner, and had touched on a variety of subjects on which he might be held by experts in the particular branches alluded to to be erroneous in his views.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

AT a recent meeting of this society Dr. L. RÉNON read a paper on the

Therapeutic Action of the Salts of Radium and Mesothorium.

During the last ten years he had employed the sulphate and bromide of radium and the sulphate and bromide of mesothorium in doses ranging from 1 to 300 microgrammes by mouth or in subcutaneous, intravenous, intrapulmonary, intratracheal, intraperitoneal, intraspinal, and intrapleural injections. He had also studied the effect of these salts upon cultures of various micro-organisms and on experimental tuberculosis in the rabbit. His investigations had shown that the treatment was harmless and that it had a definite analgesic effect, and might be advantageously used in gonococcal arthritis and chronic rheumatism. It might also be employed, in addition to other remedies, in such affections as tuberculosis, in which it sometimes caused an improvement of the general condition with fall of temperature, but without any influence on the subsequent evolution of the lesions.

Treatment of Diarrhœa and Mucous Colitis by Zinc Oxide.

Dr. G. Durand and Dr. H. Dejust stated in a communication on this subject that they regarded oxide of zinc as preferable to the astringents usually prescribed in acute diarrhœa, in which it exercised a precipitating action on mucin and serum albumin. It also possessed antispasmodic properties. Successful results were also obtained with the drug in the treatment of mucous colitis. It could be given in combination with small doses of opium, especially if the colic was very severe or the diarrhœa excessive. The daily doses varied with the cases. In acute diarrhœa it was best to begin with 2 g., divided into ten pills of 0·20 g. each. The daily amount should then be reduced by one or two pills daily, according to the rapidity of the results obtained. In chronic diarrhœa, in which the drug would have to be continued for a longer period, smaller doses would have to be employed—e.g., six pills each containing 0·20 g. daily.

Treatment of Oxyurids by Sulphurous Acid.

Dr. G. Leven in a paper on this subject described a method which he had successfully used for many years. Every evening for a period of five days the bowel was washed out and a rectal injection of eau d'Enghien, slightly warmed, was given slowly and retained. In the adult half a bottle should be used and in the child a quarter of a bottle. The injections were then omitted for four or five days and then resumed for a second or third time if necessary, as long as there were oxyurides in the stools.

Dr. G. Rosenthal described his method of

Intercrico-thyroid Injection with a Curved Needle.

In cases in which it was unnecessary to keep a permanent tube in the trachea he employed a curved needle and cannula, which he introduced into the intercrico-thyroid space. After local anæsthesia with novocain he injected the drug required. The method was specially useful for the injection of adrenalin in hæmoptysis and in asthma.

Employment of Fluoride of Ammonium in Therapeutics.

Dr. Bourgois in a paper on this subject stated that for the last 30 years he had made a careful study of the fluorides of sodium and ammonium. He had chiefly employed the ammonium salt owing to its greater solubility, but the two fluorides were of equal therapeutical value. The conditions in which ammonium fluoride was most useful were pulmonary tuberculosis, acute bronchitis, asthma during the first six or 12 months, the early stages of bone and joint tuberculosis, the prodromal stage of meningitis, gastro-intestinal dyspepsia and chronic gastro-enteritis, and whooping-cough. The results were less constant in chronic bronchitis (simple or tuberculous), asthma of long standing, and chronic arthritis and osteitis.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting of this society was held at 11, Chandos-street, W., on Feb. 17th, Dr. E. E. Flemming, the President, being in the chair.—Dr. Hedda Alstrom read a paper on Mechano-therapeutics, tracing its history from the most ancient times. She showed how, at various periods, it had been held in high esteem, at others it had been looked upon with indifference, until the weight of eminent authority and the pressure of popular opinion had again raised it from oblivion. That this method of healing had not yet taken its proper place as a special branch of medicine, she thought, was due to the fact that art and science had not gone hand in hand, but art was far in advance. Hence many people of all sorts and conditions thought themselves fit to apply it, and in these circumstances it was not possible to get a high and uniform standard of knowledge and practical skill. The work varied accordingly. In many other countries medical men and women, high in their profession, specialised in it, and its theory and practice were taught at the universities. Until the same was done in England we should not get the best out of a good thing. Dr. Alstrom said that she hoped that, in the days when we had learnt that prevention was better than cure, mechano-therapy would be placed on a level with other branches of medicine.—Dr. F. Barrie Lambert then spoke on the need for medical personnel in mechano-therapy. She gave an account of the various kinds of gymnastic training carried out in England, and said that the present-day remedial gymnast was very fully trained and efficient, provided that she held the Incorporated Society of Trained Masseuses' triple qualification of massage, remedial exercises, and medical electricity. The training for the first and second required six months each, and for the third a further three months was necessary. There was also a two years' and, in some cases, a three years' course in educational gymnastics given at the five recognised Swedish training colleges in Great Britain, which included, amongst other subjects, a thorough training in games and æsthetic dancing. The better qualified the gymnasts were the more they asked for medical supervision, but few doctors had sufficient knowledge to supervise. The difficulty of finding medical officers with sufficient knowledge to supervise made the organisation of remedial clinics difficult. Dr. Lambert urged the importance of a short course for all medical students in the theory and practice of massage, remedial gymnastics, and medical electricity, and in the after-care of orthopædic cases.—Dr. A. Kellgren-Cyriax spoke of the need for the extended application of mechano-therapy. She said that Schott's treatment for hearts, Frenkel's coördinated movements for spinal cord diseases, and Cornelius's nerve massage were all adaptations from the Swedish system, and first put on a scientific basis by H. Kellgren. She discovered a method of direct manual nerve stimulation by so-called nerve frictions, and a nerve-soothing treatment by manual vibrations. She said that nerve frictions enabled one to influence every muscle or organ in the body either directly or reflexly, internal organs being stimulated through the rami communicantes of the posterior spinal nerve roots. Nerve vibrations were able to remove pain and inflammation in most cases, and it would be unfortunate if this art were lost to humanity. Dr. Kellgren-Cyriax then showed skiagrams of three surgical cases before and after treatment by mechano-therapy, as well as sphygmographic tracings of mitral incompetence and of mitral stenosis and incompetence before, during, and after treatment by passive and later by active movements. These showed return of the dicrotic wave. She said that mechano-therapy rested on a sound physiological basis, and that there was no danger in prescribing and applying it, if its laws and technique were understood.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held to-day, Friday, March 5th, in the society's rooms, West London Hospital, at 8.30 P.M., when Sir William Hale White will open a discussion on Idiosyncrasy to Drugs.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A quarterly meeting of the association was held at 11, Chandos-street, London, W., on Feb. 24th, Dr. Bedford Pierce presiding, when Dr. R. H. Steen introduced a discussion on chronic hallucinatory psychosis and its differentiation from paranoia.

HARVEIAN SOCIETY.—At the annual meeting and conversazione of the Harveian Society, held at the rooms of the Medical Society of London, the following were elected officers of the society for the ensuing year: Dr. William Hill, President; Dr. C. D. B. Hale and Mr. Kenneth Lees, secretaries. Dr. James Taylor, the retiring President, then delivered an address entitled "Neurological Jottings." The Harveian Oration will be delivered by Sir Thomas Horder, at the rooms of the Medical Society of London, on Friday, March 12th, at 8.30 P.M. His subject will be "The Diagnostic Significance of Nerve Symptoms in Acute Infections."

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—The monthly meeting of the executive council was held on Feb. 25th at 5, Vere-street, Cavendish-square, W. A letter was read in which Mr. Asquith replied to two questions put to him, on behalf of the Federation, at the Paisley by-election, in regard to the National Insurance medical benefit. Mr. Asquith agreed that there was considerable dissatisfaction in regard to the working of the Insurance Act, and pledged himself to support a demand for inquiry.

It was announced that the following societies had accepted representation and had forwarded subscriptions: The British Dental Association, the Royal British Nurses' Association, the Sydenham District Medical Society, and the Association of Medical Officers of Health. Certain individual members of the Federation were also elected. The report of the special subcommittee appointed to draw up the Memorandum and Articles of Association was received and, after amendment, approved for official submission.

Reviews and Notices of Books.

ESSAYS ON THE SURGERY OF THE TEMPORAL BONE.

By Sir CHARLES A. BALLANCE, K.C.M.G. London: Macmillan and Co., Ltd. Two vols., pp. 612. £5 5*s*.

THESE volumes are a lordly monument to the surgery of the temporal bone. The subject is dealt with comprehensively, and a valuable display of plates affords in some directions historical interest, and in others offers a possible substitute for study in the museum and post-mortem room—indeed, many of these, especially the more diagrammatic, should be of high educational value. The text, however, is the thing. It is erudite, full of ripe experience and excellent description; we have here a book which the specialist may consult, always to find something suggestive or informatory, while a great range of knowledge is opened to the more general student. The author traverses the whole history of the surgery of the temporal bone, from ancient hints of knowledge to modern practice, and includes in his scope the intracranial complications of middle-ear suppuration in very full treatment. In connexion with these there are useful excursions into the allied portions of neurology, and much excellent naked-eye pathology.

The book has been in preparation for a good many years, and, to some extent, suffers in consequence, as do all encyclopædic works, from the fact that the earlier chapters need some additions before the last is finished; and it goes without saying that points arise in a book of this magnitude on which differences of opinion exist. But the statement is always fair, and indeed possibly our only quarrel with the author would be on the ground that his modesty conceals the notable share which he has borne in the development of the surgery of the temporal bone.

With the author's plea in the preface for the better recognition of the importance of aural surgery in our teaching hospitals we most heartily agree. The status of the aural department has, it is true, improved as the result of much hard fighting on the part of the aural surgeons, but the equipment of beds is still in many of our great London hospitals pitifully inadequate, and the student is generally conspicuous by his absence. Yet there is no department of surgery which is going to be of greater value to the practitioner when he is thrown on his own resources, and none which offers better training in logical diagnostic methods and keen observation. And on the side of public service it is hardly possible to imagine a more beneficial use of endowment than the provision of additional beds for aural patients.

DISEASES OF WOMEN.

By THOMAS G. STEVENS, M.D., B.S. Lond., F.R.C.S. Eng., M.R.C.P. Lond., Obstetric Surgeon, St. Mary's Hospital, Paddington, &c. New edition, thoroughly revised and entirely reset. London: University of London Press, Ltd. 1919. With 202 illustrations. Pp. 443. 20*s*.

IN reviewing the first edition of this work we pointed out that in it gynæcology had been presented on a pathological basis, and that Dr. Stevens's reputation as a pathologist gave value to his views on the subject. The book has proved of the greatest assistance to students, and they, at any rate, have appreciated thoroughly the arrangement adopted by the author. In this new edition there has been a considerable amount of revision, and many parts have been entirely rewritten. The section on syphilis has been revised by Mr. Alfred Allport and contains a good account of the modern method of treatment. Six injections of 914 at weekly intervals are recommended, followed, when possible, by 18 months' treatment by mercury, preferably in the form of intramuscular injections of grey oil into the buttock. If the intramuscular injections are well tolerated they are to be given in courses of eight weekly injections. Such courses should be separated by one month's treatment with potassium iodide or collosol iodine and then one month's rest. A Wassermann test should then be done and mercury recommenced, even if the Wassermann test is negative. We notice that under the causes of pure menorrhagia the author includes chronic bronchitis or emphysema: surely such a cause is very uncommon.

As might be anticipated, Dr. Stevens's views on the subject of erosion are sound, and he shows very clearly that this condition is always the result of some chronic infection, and that the term adenoma applied to it by some authors gives quite an erroneous view of its etiology and pathology. Considering the difficulty most students experience in understanding how a Hodge pessary acts it is a pity the author has not elaborated his account a little more, especially in view of the misleading conceptions of its action to be found in many text-books on gynæcology. We would suggest that the diagrams illustrating the process of tubal abortion would be improved if it were made quite clear that at first the ovum is really imbedded in the wall of the tube. The index might with advantage be a little fuller, and we notice no entry under Ureter.

The book is a very good one, and may be recommended to the student as well written, not too prolix, and full of the best kind of teaching.

ATLAS OF OPERATIVE GYNÆCOLOGY.

By BARTON COOKE HIRST, M.D., Professor of Obstetrics, University of Pennsylvania. London and Philadelphia: J. B. Lippincott Company. 1919. With 164 plates and 64 figures. Pp. 292. 30*s*.

THE author has attempted the graphic method of describing operations for conditions peculiar to women by a series of coloured illustrations showing the separate steps of each operative procedure. The views expressed and the operative technique advocated are based on many years' experience. The author is opposed to the practice of smearing tincture of iodine on the skin of the abdomen, and then immediately incising it, as, indeed, are most surgeons, and the majority of those who use iodine in this country precede its use by a careful cleansing of the skin before the operation with some other antiseptic. The practice, followed by Professor Hirst, of covering the edges of the wound with a rubber dam, which is sewn to the peritoneum, is a very good one, and excludes with certainty the chances of infecting the edges of the wound, or of the gloves becoming infected by contact with the skin of the patient. The necessity for many secondary repairs of the pelvic floor could, Professor Hirst thinks, be overcome by the more frequent practice of what he terms intermediate operations performed some five days or so after delivery, and done then as completely as may be necessary. For dealing with a cystocele the interposition operation of Watkins is advised. Most gynæcologists in this country would regard this as rather a severe measure.

In the operative treatment of retroversion of the uterus the author, through a Pfannenstiel incision, both shortens the round ligaments in the inguinal canals and also, after opening the abdomen and inspecting the pelvic organs, suspends the uterus to the peritoneum with a single strand of No. 3 catgut. He states that this procedure has given him very good results. We are surprised to find that the author favours abdominal rather than pelvic drainage in cases where drainage is necessary. In discussing the mortality following Wertheim's operation, it is suggested that the more extended use of gas and oxygen anæsthesia may help to lower the immediate mortality, but nothing is said of the great advantages to be gained from a combination of spinal anæsthesia with the use of a small amount of ether; this method yields extremely good results and greatly expedites the performance of the operation. The various methods of carrying out Cæsarean section are well and fully described, and we are glad to see that the operation of pubiotomy is not recommended; it has, as stated, an interesting history, but the need for the operation has now disappeared.

Professor Hirst has produced a very good and useful atlas. It should prove of great assistance to the young operator, and it forms an interesting summary of the operative methods of a distinguished American obstetrician and gynæcologist.

A MANUAL OF HYGIENE AND SANITATION.

By SENECA EGBERT, A.M., M.D. Seventh edition. Philadelphia and New York: Lea and Febiger. 1919. With 160 engravings and 5 plates. Pp. 554.

THE present is the seventh edition of this work, and, like its predecessors, it contains a clear and concise statement of the fundamental principles of hygiene and sanitation. Perhaps no branch of medicine has advanced more rapidly in recent years than that of public health, and opportunity has therefore been taken by the author, in issuing a new and enlarged edition, to revise the text and bring it thoroughly up to date. Special attention has been devoted to the chapters on sewage disposal, industrial hygiene, and military hygiene. The first of these subjects is developing rapidly in importance in the United States of America on account of the growing realisation of its influence upon the health and comfort of communities, both large and small. The second is likely to come more and more into prominence in view of the extensive expansion of industrial enterprise which may be expected to take place after the war, while the third is of interest to the student of public health because of the important part which it played in the recent world war. There are besides chapters on bacteriology and parasitology; the atmosphere; ventilation and heating; water; food; stimulants and beverages; personal hygiene; school hygiene; disinfection; quarantine; vital statistics; the examination of air, water, and food.

The illustrations are, for the most part, excellent, serving to elucidate the subjects to which consideration is given. The book may be confidently recommended for the use of students and all, indeed, interested in public health.

PYE'S ELEMENTARY BANDAGING AND SURGICAL DRESSING.

With Directions Concerning the Immediate Treatment of Cases of Emergency. By V. ZACHARY COPE, B.A., M.D., M.S. Lond., F.R.C.S. Eng. Fourteenth edition. London: Simpkin, Marshall, and St. John Ambulance Association. Bristol: John Wright and Son. 1919. Pp. 232. 3*s.* 6*d.*

THIS well-known book is a reprint of a portion of Pye's "Surgical Handicraft," the present issue being adapted from the eighth edition of that work by Dr. W. H. Clayton-Greene. Within its scope the book is complete, and forms a useful compendium of information for the beginner, whether medical student or nurse, in the wards of the hospital or in the casualty room.

TRAITEMENT DU DIABÈTE SUCRÉ.

La Cure de Bouchardat. Par F. RATHERY, Professeur Agrégé à la Faculté de Médecine de Paris; Médecin des Hôpitaux. Paris: Librairie Félix Algan. 1920. Pp. 276. 8 fr.

THE knowledge and management of diabetes in France during the last half-century have not made the progress which might be expected in the country of Claude Bernard. With the exception of the treatment by fasting and purgation proposed by Guelpa on empirical grounds, no important contribution to the subject has been added by French physicians in recent years, and, judging by the contents of the volume under review, tradition still holds sway. Dr. Rathery's book is avowedly a résumé of the ideas and methods of A. Bouchardat, based partly on that physician's "De la Glycosurie ou Diabète Sucré," published in 1883, and partly on oral information transmitted by his son to Dr. Rathery, his stepson. Where modern views on the ætiology and pathology of diabetes are mentioned it is in order that credit for their anticipation may be given to Bouchardat, and, as the title indicates, the treatment advocated is the modified Rollo method devised by him; other forms of treatment are not mentioned or are dismissed with brief notice. Bouchardat is rightly classed as one of the most brilliant physicians in the history of diabetes; he revived and transformed Rollo's crude and unscientific methods, invented gluten bread, and introduced the intelligent use of exercise for diabetics, beside making important contributions to the pathology of the disease. But we think that he would have acknowledged that his methods were capable of improvement and likely to be modified in the light of further discovery. Ancestor worship does not make for progress, and the truth of this statement is exemplified by Dr. Rathery's book.

THE PRINCIPLES OF NURSING.

By C. A. BROWN, R.N. Philadelphia and New York: Lea and Febiger. 1919. Pp. 262.

As the author rightly states in her preface to this book, it is essentially elementary, but may prove of substantial value to nurses in their first year of training. In addition to outlining the underlying principles of nursing, the author has successfully conveyed to the student nurse a little of the finesse to be achieved in nursing, and how this can be done under conditions often far from ideal. There are valuable chapters on Anæsthetics and the Post-operative Care of Patients, two subjects the importance of which is often overlooked or minimised in text-books for nurses.

The arrangement of matter might have been improved upon, as terms which are used in describing treatment are often explained many chapters ahead; and sometimes, indeed, these terms are not explained at all. It is to be regretted that the system of cross-indexing has not been employed, for this would have increased considerably the value of the book.

The absence of detail, which is essential to the more advanced student of nursing, makes the book of little value to nurses preparing to enter their final examinations, but it should help considerably to prepare those entering a training school for the responsible duties which lie before them.

HEALTH IN THE HOME.

By A. KNYVETT GORDON, M.B., B.C., B.A. Cantab. London: Jarrolds, Ltd. 1919. Pp. 245. 5*s.*

THE author's aim is to place before non-medical readers a brief account of the meaning of the symptoms of disease, with the object of assisting in its prevention and of enabling the sufferer or his relatives to appreciate in a general way what may be the matter. Like a quarrel, getting well needs two parties, and coöperation between these parties is essential. In this direction Dr. Gordon's book is useful, indicating, as it does, the best way in which to prevent disease, beginning from the care of the young. The first part of the book deals in broad outline with the mechanism of the body, and with the general conception of health and disease; the second discusses various symptoms of disease, pain, cough, vomiting, fainting, and so forth, and touches upon infections, venereal diseases receiving only a passing reference. In the third part, dealing with domestic hygiene, stress is laid upon the care of the young, faulty methods at this stage of life being recognised as the cause of much avoidable sickness and distress in after years. An appendix gives receipts for invalid recovery, and the caloric values of common foods with specimen menus.

THE METALS OF THE RARE EARTHS.

By JAMES FREDERICK SPENCER, D.Sc. London: Longmans, Green, and Co. 1919. Pp. 280. 12*s.* 6*d.*

THE history of the discovery of the rare earths, as described in this volume, makes very interesting reading. Although so far these substances have little significance in medicine they may well gain in this direction in the future. The importance which some of them have assumed in the commercial world is well known. The best example, perhaps, of rare earths coming into wide service was when the gas incandescent mantle was made from the rare earths thoria and ceria, a discovery which saved the gas industry from disaster as a source of illuminating power, in face of the rapid improvements developing in electric methods of lighting. In the chemical world, also, some of the rare earths are taking their place as eminent catalysts, effecting combinations with ease, economy, and rapidity, succeeding processes which before were tedious. The book gives particulars of these technical applications, and records as well the processes by which the rare earths are separated and the analytical methods for their estimation.

JOURNALS.

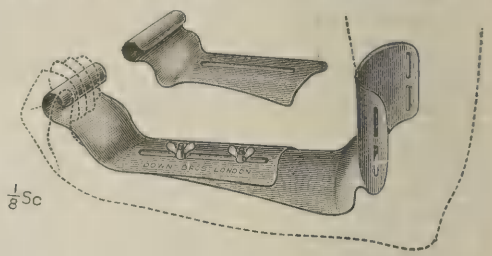
Tubercle. A Monthly Journal Devoted to All Aspects of Tuberculosis. Vol. I., No. 5. February, 1920.—In the February number Dr. Morriston Davies leads off with a Consideration of the Treatment of Pulmonary Tuberculosis by Surgical Intervention, devoted mainly to those procedures which are applicable when artificial pneumothorax has failed owing to adhesions. Resection of ribs and rib cartilages may be employed when general collapse of the lung is aimed at, while two procedures—(1) replacement by a foreign body when collapse of the upper lobe is desired, and (2) section of the phrenic nerve in order to collapse the lower lobe—are also discussed. The latter operation is especially of use when severe cough is due to diaphragmatic adhesions. Another operation—viz., limited artificial pneumothorax by injection of oxygen—is recommended for relief of obstinate pain in cases of dry pleurisy.—Dr. H. A. Ellis follows with an article on dispensary treatment, in which he maintains "that this method of controlling pulmonary tubercle is on the right lines must be admitted when the diminished death-rate from adult male tubercle in Middlesbrough is realised." These deaths numbered 95, 88, 81, 81, and 69 in the years 1914–18 in spite of a large increase of population. Taken alone the figures are impressive, but we find from the report that the total deaths from pulmonary tubercle varied little, owing to a rise in the female deaths, consequent on war conditions. An encouraging report is quoted from Dr. Tennberg, giving the results of ten years' experimental trial of dispensary methods in a certain parish in Finland, and the report is the more valuable because the wholesale examinations of the population at the beginning and end (1909 and 1919) were carried out by the author. There was special concentration on child welfare, and, while the incidence of pulmonary tuberculosis among the general population was reduced more than 50 per cent., the best results were obtained in early life. Among the abstracts is a series on chemotherapy reporting good results from the use of cyanocuprol, and in pneumococcic complications of optochin. Copper sulphate (1 in 1,000,000) has been used effectively for some years in clearing ponds of offensive algæ without harm to fish (so far as reports go), and the results of the therapeutic use of copper will be watched with great interest. A critical review deals further with this agent and the history of its employment. The number closes with valuable reports of lectures and meetings.

Bulletins et Mémoires de la Société Médicale des Hôpitaux de Bucarest. Nos. 1–8.—Whatever may be the physical difficulties of life in the Near East, it is clear that the science of medicine is not neglected. The first number of this bulletin appeared within four months of the signing of the armistice, and since its first appearance one number has been published monthly, excepting during the vacations. Each number contains two or more communications made at the previous session of the society. Papers dealing with typhus and pellagra make interesting reading to those who are not in daily association with these diseases. The last number to reach us contains an article on the Ætiology of Dementia Præcox, in which the author, Dr. A. Popéa, is "strongly inclined" to credit syphilis with being the cause of this disease. His argument depends largely on the results of Wassermann tests which are not sufficiently numerous to be convincing. The argument suffers, too, from the absence of any control experiments on the normal population. Also we are a little surprised to hear dementia præcox described as "bien isolée en clinique." The bulletin is printed throughout in French and several of the advertisers have addresses in Paris, which suggests that the journal is intended for consumption in France as well as in Roumania. Subscriptions, 40 lei, are received by Dr. Alexandresco-Dersca, Bd. de la Catargi 2, Bucarest.

New Inventions.

A NEW SPLINT FOR COLLES'S FRACTURE.

IN the treatment of Colles's fracture, good results are often obtained by flexing the wrist sharply—e.g., over an anterior rectangular splint. This method is specially valuable in cases in which the lower radial fragment shows a tendency to rotate backward. Given perfect reduction, and skilled after-treatment, the full normal range of flexion and extension will always be recovered; and pronation will be unimpaired also, because the hand was put up fully pronated. Supination is not a common movement, and therefore it tends to become limited, unless especial care is taken to cultivate it. The splint here illustrated is expressly devised to prevent any loss of supination, whilst retaining all the advantages of the older methods. It consists essentially of an anterior flexed-wrist splint, combined with an arm-piece which keeps the forearm fully supinated. It is made of light sheet-metal, and is adjustable for any length of forearm; the wrist is bent to a suitable angle, and a comfortable rolled lower edge is provided for the fingers to grip. It will be found that one or other of the two hand-pieces provided will fit any patient who has a Colles's fracture. It is of the utmost importance that the fracture should be fully reduced before the splint is applied; the latter should be padded with a single layer of Gamgee tissue or thin felt, and fastened on by webbing bands round the arm and forearm and a piece of strapping or bandage round the metacarpal region. The position is not in the least irksome, which is not the case with other supination splints. Generally speaking, the splint should be removed for good in a week's time, and massage should be employed from the very first. With perseverance all movements should be completely restored.

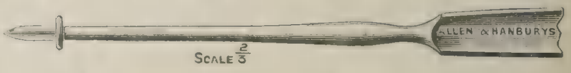


The splint has been made for me by Messrs. Down Bros. ALAN H. TODD, M.S., B.Sc. Lond., F.R.C.S. Eng.
Portland-place, W.

TONSIL BAYONET

FOR OPENING PERITONSILLAR ABSCESSES.

IN opening peritonsillar abscesses it is usual to employ one of the following instruments: (1) a small scalpel guarded with strapping; (2) unguarded forceps. When employing the scalpel it is difficult to sterilise the strapping; in the case of the unguarded forceps it is easy to go too far in searching for deep pus. With the idea of overcoming these two disadvantages I have had made for me the instrument here figured and claim for it the following advantages: (1) Ease of sterilisation; (2) the presence of a collar, which prohibits the operator stabbing too deeply; (3) the double-edged bayonet, which facilitates the conversion of the stab into an incision in either an upward or downward direction. The operation can then be completed with blunt forceps quite safely.



Messrs. Allen and Hanburys are the makers of the instrument. A. SCOTT GILLETT, F.R.C.S. Edin.
Connaught-square, W.

THE LANCET.

LONDON: SATURDAY, MARCH 6, 1920.

A Physical Census.[1]

FROM the point of view of national health there has within the last few days been published, as from the Ministry of National Service (1917–1919), a document of the highest importance—namely, a first Report upon the Physical Examination of Men of Military Age by National Service Boards from Nov. 1st, 1917, to Oct. 31st, 1918. If Sir AUCKLAND GEDDES, himself a medical man, had during the war accomplished nothing else than inaugurate the scheme under which this physical census of the people has been taken, the nation as well as the medical profession would owe to him a deep debt of gratitude for a vast public service. Now, for the first time, there is provided for us a mass of material worked out upon a uniform system, which throws clear light upon the physical condition of the manhood of England, Scotland, and Wales, and upon the effects of industrial life and occupation upon the well-being of our people. Those effects are seen to be so pronounced that action must follow.

We deal for the time being only with a consideration of the circumstances leading up to the physical census of 1917–18: the quality of the material presented for examination, the method of examination, and the value that may safely be attributed to the results obtained. Great as was the work performed by the R.A.M.C. during the war from the immediate start, no one will deny that in the matter of the physical examination of the recruit the organisation began imperfectly. There was no adequate attempt to standardise the work of the medical boards; there was not even a published code bringing up to date from time to time the instructions issued regarding acceptance and rejection of the recruits. As the war went on, and the country, gradually awakening to the magnitude of the efforts necessary to avert destruction, evolved and improved its organisation for war, the prime importance of the man-power of the nation received adequate recognition. Month by month, week by week, it became increasingly clear that the demand of the various armies for men must be paramount, although the need for keeping the vital industries of the country adequately supplied with sufficient personnel was as essential to ultimate success as the supply of fighting men. In due course, so urgent became the need, industries hitherto protected were "combed out" in response to the insistent demands of the fighting forces for men. In the past the medical boards had been attempting to perform two functions: (1) to determine whether a man was or was not physically fit to enter the army; (2) to classify the men, whom they considered sufficiently fit, for some form of service in categories from which they could readily be posted to suitable corps and army units. Owing to the absence of clear-cut instructions and lack of training of the medical officers appointed for these duties in standardisation, it will be remembered that the action of the boards had to bear severe criticism. Then, under the Military Service Act of 1917, with the introduction of compulsory military service, the Government withdrew the matter of categorisation from the army and placed it under the control of the Minister of National Service, who forthwith proceeded to organise the physical examination of the men called up, placing the task under the direction of Sir JAMES GALLOWAY and a small but carefully selected committee. The country was divided into regions, and Commissioners were placed in charge of each, with Deputy Commissioners and staff under them. The Deputy Commissioners were brought together and trained so as to take coördinate action and arrive at a common agreement regarding the categorisation of doubtful cases; a clear and admirable code of directions was placed in the hands of every member of the new boards, and all endeavour was made to bring it about that, from one end of Great Britain to the other, the physical examinations were conducted under a single standard.

The new boards began action upon Nov. 1st, 1917. As a result, during the fourth year of the war—the year under review—there came up for examination by the boards (1) a large body of men in protected industries, where in the nature of things an abnormally high proportion of the physically fit were employed; (2) men previously rejected, when the need was less urgent, and now called up for re-examination; (3) men now refused for exemption by tribunals, owing to the urgent demand occasioned by the military situation; (4) a large number of lads who attained the age of 18 during the year; and (5) a relatively small number of men between 41 and 51 who during the year (in April, 1918) became liable for military service under the Military Service (No. 2) Act. The material examined and re-examined during the year under review consisted altogether of close upon two and a half million men, and, as everyone knows, the resulting classification was a shock to any complacency which this country may have felt in its national physique. For while only 10 per cent. were rejected as totally and permanently unfit, not more than 36 per cent. were passed as possessing a full normal standard of health, leaving 54 per cent. to be divided between two classes whose members manifested some or marked physical defects. The reasons underlying the classification are given, as far as they have yet been published, in a document which all should study closely and which will come under further review. We note with pleasure this passage closing Sir JAMES GALLOWAY'S official letter, presenting the report of his Committee to Sir AUCKLAND GEDDES—

---

[1] Report upon the Physical Examination of Men of Military Age by National Service Medical Boards from Nov. 1st, 1917–Oct. 31st, 1918.

> Until the end of March, 1919, the Committee acted under your direct instructions as Minister of National Service with Dr. H. W. Kaye, the personal assistant of the Chief Commissioner of Medical Services, as Secretary. When the Medical Department of the Ministry of National Service finished its work the responsibility of carrying on our investigations devolved entirely on our Secretary.
>
> The Committee now desire to express their high appreciation of the enthusiasm and perseverance shown by Dr. Kaye in carrying forward our work to the stage reached in this Report. We desire also to take this opportunity of recognising the valuable work of the Commissioners and Deputy Commissioners of Medical Services and the numerous members of our profession throughout the country; their observations form the basis of the whole Report.

The praise thus meted out has been thoroughly well deserved.

The Reproach of Psychiatry in England.

OF all the branches of medicine psychiatry seems still to suffer from that relative neglect and to labour under those disadvantages which tradition assigns to the lot of the youngest sister. From time to time the calm of apparent stagnation is ruffled by some breeze of public agitation seeking to direct attention to defects, administrative or otherwise, yet such superficial disturbance bears little proportion to the immense undercurrent of dissatisfaction running strongly, within the profession itself, in the minds of all who have the interests of psychiatry in England at heart. If we inquire the reasons of this they are found to reside in a combination of factors on which stress has been laid repeatedly, with as yet little obvious result. It is imperative that the fons et origo of the dissatisfaction, which percolates through all the strata of asylum life, should be clearly laid bare, else the stream will continue to run muddily. It will, we believe, be granted that the scientific health of the asylum unit—that is, of the medical staff—takes its tone from the superintendent; should he be keen on the advancement of psychiatric learning, his subordinates find themselves in a stimulating atmosphere the influence of which is reflected in the actual treatment of the inmates, as well as in the contributions from the staff to the body of psychiatric doctrine. On the other hand, if the senior has been selected more for social than for scientific equipment, or should he allow himself to be more concerned with the asylum laundry or meat-supply than with the healing of the mind, not only is the general scientific level of the institution lowered, but any junior medical officer is only too apt to find his youthful enthusiasm starved in an uncongenial environment; he sinks to the humdrum level of those with whom he is inevitably in such close association. The asylum officer who can rise superior to depressing surroundings is the exception. We should be the last to belittle the importance of social and administrative gifts in the smooth running of the asylum communities of the country, which from their very nature must be self-contained and self-sufficient, but psychiatry exists as a branch of medicine for the prevention and cure of mental disease, and nothing can ever be permitted to usurp this function. No elaborate schemes of internal decoration, no ingenuity of kitchen appliances, no perfectly fitted miniature theatres or admirably supplied gardens, farms, and piggeries, can make up for indifference to clinical and pathological reports, neglect of modern technique in treatment, or absence of stimulus to increase the annual percentage of cures or relief.

The promotion or advancement of a medical officer, further, sometimes seems to depend so little on his professional knowledge that he has scant inducement to devote himself to an earnest study of the subject. His work is too often seen to begin and end with the discharge of routine—essential duties which fatigue without stimulating—and with the accomplishment of which any incentive to personal research vanishes. When he has time to think over things he fully realises the tremendous material at his disposal, the fascination of the study of the complex case, the therapeutic problems with which he is surrounded, yet evening finds him unable or disinclined to sit down to serious work. There is, however, another reason for the paucity of scientific output. Friendly conversation with the average asylum medical officer has often elicited the confession that he does not know how or where to begin his task; he is conscious of not being abreast of knowledge in many instances, and is sorely in lack of a guiding and advising mind. If this position be analysed it will be seen to derive from the fact that so few centres for the organised teaching of psychiatry exist, and the equipment of some leaves much to be desired. Of how many of our asylum officers can it be said that they have attended courses of theoretic and practical psychiatry at home or abroad? When do they get a four or six weeks' leave of absence to follow post-graduate instruction in their life's work at a recognised centre? Nay, how many of them have ever spent an unforgettable Wanderjahr in foreign school or laboratory prior to their entering on their professional career of psychiatric expert? Not that foreign experience of itself confers a cachet unobtainable at home, for our home material, in no way inferior, is calling out for investigation and research; but as long as our young medical officers drift untrained into asylum work, so long will the reproach continue that in this country psychiatry is not adequately studied.

On other occasions we have spoken of the peculiar restrictions and handicaps of certain phases of asylum life for the junior staff; we are more concerned for the present to appeal emphatically for better chances for training, better facilities to keep abreast of scientific advance, greater endeavour to make the first step on the ladder encouraging, more serious efforts to utilise precious time and valuable stuff. Is it too much to hope that the authorities who control asylum affairs should one day claim a certain standard of professional attainment on the part of medical officers entering the service, and insist similarly on granting members of asylum staffs post-graduate leave? We are confident that the outlook is bright in reality, and that the stirring among what only the cynic would call the dry bones augurs well for the future. We can imagine a central authority fully conversant with the best methods employed in the whole range of the practice of psychiatry and able to give local bodies information and guidance as to management, equipment, and expectation of output on the scientific side no less than on the others; we can foresee the day when prophylaxis and prevention will be elevated to their true importance by the establishment of clinics and observation wards staffed by trained men with all-round experience. The problem confronting us is the elaboration of the best way to organise and utilise the sources of psychiatric energy which, we are convinced, are only waiting to be tapped.

Thyroid and Sex Development.

WIDESPREAD interest appears to have been aroused by recent articles in the daily press, in which somewhat highly coloured descriptions have been given of experiments by Mr. JULIAN HUXLEY and others on the effects of administering thyroid extract to animals. Although the beneficial effects of thyroid extract in cretinism and myxœdema have long been known, there still remains much to be discovered in regard to the functions of the thyroid and other ductless glands, and it is to be hoped that Mr. HUXLEY'S work may assist towards clearing away the obscurity which surrounds them. It cannot be expected, however, that the work of even the most brilliant investigator will immediately unravel the complicated inter-relations which undoubtedly subsist between the various "endocrine" organs, and still less is it likely that the result will provide for mankind an "elixir of life" or prescription for perennial youth. Mr. HUXLEY'S experiments, if we may trust the daily press, confirm and amplify the conclusion reached by previous workers on the subject that the thyroid plays an important part in bringing about the metamorphosis in amphibia, and this is doubtless but a special case of the intensification of metabolic and developmental processes known to be induced by the thyroid hormone. There is also good reason for the belief that the same hormone is concerned with the onset of sexual maturity, and it has even been suggested that, in Amphibia at least, it may play a part in the determination of sex itself. For it has been observed by R. HERTWIG and others that when the fertilisation of frog's eggs is delayed much beyond the normal time, a greatly increased percentage of male tadpoles is produced, and ADLER recorded that these tadpoles had hypertrophied thyroids. It seems unlikely, however, that this conclusion, even if substantiated for Amphibia, can be of general application, for the evidence that sex is determined in very many cases by the presence or absence of a definite "sex-chromosome" is now overwhelmingly strong. It is conceivable, however, that the sex-chromosome may cause the production of a hormone which is the more immediate agent in sex determination, and that in Amphibia, and possibly other animals, its effect may be imitated by the thyroid secretion.

The part of the subject in which our knowledge is most imperfect is that concerning the relations of the thyroid and other endocrine secretions to the hormones produced by the genital glands themselves. Much evidence has been obtained in recent years that the appearance of secondary sexual characters is largely determined by secretions from the ovary or testis, and the work of LILLIE on twin fœtuses in cattle, in which the fœtal membranes and blood systems become confluent, indicates that an originally female embryo can be converted almost into a male by the testicular hormone derived from its twin. But that these sexual characters are not determined by the secretions of the genital glands alone is proved by the existence, in birds at least, of gynandromorphs, which have male characters on one side of the body and female on the other. Nor is it certain that all the effects produced are due to the genital hormones directly, for it has been suggested that these may act in an indirect manner by stimulating the thyroid, the pituitary body, and perhaps other ductless glands to produce greater or less amounts of secretion; thus in respect of some sexual features at least it is these latter substances that may be the effective agents. It seems clear, therefore, that although we have considerable knowledge of the effects caused by insufficiency of any one of these glands, and are therefore able to a large extent to supply the remedy, we are still far from a complete understanding of their combined action or of how their activity is correlated. Some of the articles we have seen in the lay press, dealing with Mr. HUXLEY'S investigations, suggest that knowledge has gone much farther, and to this extent have been misleading.

Rewards for Medical Discovery.

THE deputation from the British Medical Association and the British Science Guild which, along with representative medical Members of Parliament, waited on Mr. BALFOUR on Tuesday afternoon, was sympathetically received by the Lord President of the Privy Council. The deputation suggested the allocation of a sum of £20,000 a year to be divided among medical discoverers who benefit their fellow-men without themselves deriving pecuniary benefit therefrom. Mr. BALFOUR unerringly singled out the chief difficulty in such a scheme—namely, that of deciding equitably on the actual originator of a discovery. Medical science is essentially evolutionary, the departures of the present being alike founded on the knowledge of the past and directed towards the developments of the future. Many will be constrained to agree with Mr. BALFOUR that a better way is to make the life of the investigator less hard, and his work an end in itself. We welcome the encouragement, implied in Mr. BALFOUR'S words, of the endowment of research, though it is easy to see that, even with such endowment, medical discoverers might frequently go unrewarded.

Annotations.

"Ne quid nimis."

ROYAL ARMY MEDICAL CORPS WAR MEMORIAL.

A REPRESENTATIVE Committee has been constituted to put into execution a scheme for erecting a permanent memorial to the officers, non-commissioned officers, and men of the Royal Army Medical Corps who fell in the war. The Committee numbers on its body members of the Regular, the Special, the Reserve, the Territorial, and the Civilian Medical Services, to whom have been added the Presidents of the Royal Corporations and the past and present Director-Generals of the Service. Ireland, Scotland, England, and Wales are all voiced on the Committee, and at a large and authoritative meeting the following decisions have now been agreed to:—

1. That a permanent memorial should be erected in London, with replicas in Edinburgh and Dublin, if funds were available.
2. That the names of officers, non-commissioned officers, and men who had fallen in the war should be inscribed on the memorial.
3. That funds "ear-marked" for the benefit of families should be devoted to that purpose.
4. That it should be open to the public to subscribe such sums as they wish.
5. That subscriptions should be sent to the honorary secretary, R.A.M.C. War Memorial Fund, Captain A. R. Wright, D.S.O., War Office, Cornwall House, Stamford-street, S.E. 1.

We need not point out how heartily we sympathise with this movement, and we are glad, also, to see that public subscriptions will be admitted. We shall be surprised if a war memorial to the Royal Army Medical Corps does not receive support from the public, who have appreciated the splendid share which the Corps took in the war, and who, to some extent, are aware of the professional and private sacrifices made by many thousands of doctors at the call of the country. The decision of the Committee that funds can be ear-marked for the benefit of the families of the fallen is a wise one; it may be that a large proportion of the money received will be designed for this object.

INFLUENZA, HERE AND IN U.S.A.

THE Ministry of Health has communicated to the press a statement as to the position of epidemic influenza at home and in the United States. Influenza is epidemic in many large American cities, and the disease is of the same kind as was observed in 1918–19, except that the proportion of severe or fatal cases in persons attacked is appreciably smaller. The vital statistics of England and Wales exhibits the following features, the Ministry state:—

(1) The weekly totals of deaths attributed to influenza in London and the 96 great towns have, on the whole, tended to increase, but the absolute increments are so small and the necessary uncertainty of classification so great that no unfavourable inferences can be drawn from these fluctuations.

(2) The returns of notified cases of pneumonia have exhibited an appreciable increase, too large to be set down as a mere chance fluctuation. The system of notification, however, has not been in force long enough to allow of comparison with the experience of a normal year; hence an uncertain proportion of the undoubted increase may be due to customary seasonal variations.

(3) There are no indications of epidemic influenza in any of the large factories situated in various parts of the country which furnish special returns to the Ministry. On the other hand, there is proof of the existence of epidemic influenza of an infectious but relatively non-fatal type in certain large schools situated in the south and south-west of England. Measures have been taken to deal with these outbreaks upon the general lines indicated in the previous communiqué.

It is apparent from these circumstances that influenza is epidemic in a few localised English and Welsh communities, and that the type is similar to but less severe than that of 1918–19. While this is a very different situation from that occurring in American cities and in certain parts of Europe, the Ministry is none the less anxious that the public should take heed to the possibilities. The increase of the number of notified cases of pneumonia, and the existence of epidemic influenza in certain schools, make it advisable to direct attention to the importance of attention to the measures already advised to be taken,[1] advice which has been followed widely by public health authorities and the medical profession, when concerting appropriate measures to deal with emergencies.

A NEW MONTHLY JOURNAL OF EXPERIMENTAL PATHOLOGY.

IT is a remarkable fact that such a vigorous branch of medical science as pathology has hitherto been served in this country by only one special journal, which, appearing quarterly, has naturally been unable to publish more than a modicum of the regular flow of articles on pathological subjects. The consequence of this is to be seen in the scattering of such scientific communications through almost every kind of medical publication. Absence of ready reference and delay in the appearance of original work have impeded the natural growth of pathological science, and any attempt to remove such obvious drawbacks to progress is welcome. The *British Journal of Experimental Pathology*, the first number of which has just been issued, is a determined attempt to fill the gap. We are glad to see that the editors construe pathology in its broadest sense; they propose to disseminate knowledge gained by the experimental method, whether in bacteriology or physiology or bio-chemistry, in so far as it may contribute to our understanding of the nature of disease. In this way the journal will undoubtedly meet the needs of research workers, whether in the laboratory or at the bedside. We understand that a happy coöperation with workers in overseas dominions will be kept up in the journal, to which we wish a successful career.

LOCAL OPTION IN INSURANCE PRACTICE.

THERE has been an interesting side-current in the discussion on the new terms of service under the Insurance Acts. In the reports received from a number of areas may be noted a great measure of unanimity between the professional committees on the one side and the insurance committees on the other. In many areas these committees have agreed upon certain modifications in the regulations, especially in regard to the schemes for remuneration and allocation. But the professional representatives, who have been successful in carrying their lay committees with them, are naturally disappointed when they find that the Ministry of Health is unable to accept their modifications because they contravene either the Statutes or the regulations which have been framed under them.

---

[1] THE LANCET, Jan. 31st, 1920, p. 270.

This is absolutely no reproach to the Ministry, but none the less local negotiations have been felt to be useless. In certain areas, and notably in Sheffield, protest has been made over the loss of time and trouble involved in the refusal of the central department to sanction arrangements agreeable to both the contracting parties on the spot, but the situation was not clearly understood. We believe that it would be well for the medical profession to realise that, for the present at least, agreements between panel and insurance committees can only deal with modifications in detail of the administrative machinery, or, in other words, with the methods of carrying out the settled principles underlying the regulations. It is true that alterations in the regulations themselves have been made upon the suggestion of local medical committees, and secured in the conferences between the Ministry of Health and the Insurance Acts Committee. But local committees are apt to be late in the field, and to forget that their opportunity for altering the regulations in principle lasted only so long as these were in draft, and that the mechanism for doing so was provided by the resolutions passed in the Conference of Local Medical and Panel Committees. We regard the rapprochement between the local medical and lay interests, as evinced at Sheffield and elsewhere, as of happy augury for the smooth and effective working of medical benefit under the Insurance Acts. But these protagonists of the Whitley principle must bear in mind that their brethren in general, both medical and lay, have not been willing to give up the carnal weapon of collective bargaining; and they cannot have it both ways. But their time will come, for the whole future of medicine is bound up with smooth and efficient local working, and the Ministry of Health in taking over the Local Government Board had no quarrel with the local government principle.

THE DANGER OF PISTOLS.

AT a recent inquest in the Paddington coroner's court held upon the body of a demobilised officer, who had shot himself with a revolver in an hotel, the coroner said that he intended to call the attention of the authorities to the case. It showed, as he pointed out, that the deceased, though he had left the army and gone into civil employment, had been in the habit of carrying about with him the Service revolver with which he took his life. He had no gun licence and probably many others also carried pistols without licences in the same way. Everyone will agree with the coroner for Paddington that the carrying of pistols in the streets is a dangerous habit. Attention was called in THE LANCET frequently to the practice for many years before the war. The danger then arose chiefly from the selling to boys and irresponsible persons of cheap pistols, dangerous toys rather than military weapons, and the restrictions of the Pistols Act were designed to check, if possible, this unnecessary traffic. The situation is now different. There must be a great many weapons of a large type, taking service ammunition, in the possession of private individuals who may justly claim that crime is prevalent and that they are necessary for their protection—for example, in a country house or suburban villa. They would naturally point also to such cases as the recent murder of a policeman at Acton, and argue that the undiscovered murderer was able to carry a revolver without detection, and that the honest householder has a right to arm himself adequately even when out of doors as long as dangerous criminals carry weapons. The revolver has figured in a large number of crimes recently, including the holding up of banks and the murder of Mrs. Breaks. It is very desirable to restrict its use, as the coroner at Paddington urged, by strengthening the existing law, but it is a difficult thing to suggest precisely where the law should be strengthened. Severe penalties for carrying revolvers are urged by some, but the difficulty is to detect the persons who carry them before they are arrested for some crime, which in itself would enable them to be severely punished. The formalities attending the sale of revolvers only affect cases where a weapon is bought from a trader; it is impossible to restrict private transfers between individuals. Of course, if the criminal classes could be prevented from carrying firearms, the claim of other citizens to possess them for the defence of their persons and property would have less justification.

THE SELECTIONS FOR FELLOWSHIP OF THE ROYAL SOCIETY.

THE Council of the Royal Society decided recently to recommend for election into the Fellowship of the society the following 15 from the list of candidates:—

Dr. Edward Frankland Armstrong, Sir Jagadis Chunder Bose, Dr. Robert Broom, Professor Edward Provan Cathcart, Mr. Alfred Chaston Chapman, Dr. Arthur Price Chattock, Mr. Arthur William Hill, Dr. Cargill Gilston Knott, Professor Frederick Alexander Lindemann, Dr. Francis Hugh Adam Marshall, Dr. Thomas Ralph Merton, Dr. Robert Cyril Layton Perkins, Professor Henry Crozier Plummer, Professor Robert Robinson, and Professor John William Watson Stephens.

THE ANNUAL CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

THE Royal Institute of Public Health will hold the Annual Congress for 1920 in the University of Brussels from Wednesday, May 19th, to Monday, May 24th, 1920, on the invitation of Monsieur Adolphe Max, the Burgomaster of Brussels, and the rectors of the various Belgian universities, Viscount Sandhurst, Lord Chamberlain, presiding. The scientific work of the Congress will be carried on under the following sections:—

(1) State Medicine: President, the Right Hon. the Lord Dawson of Penn; (2) Naval, Military, Tropical, and Colonial: President, Surgeon Rear-Admiral Sir Robert Hill, Medical Director-General of the Royal Navy. (3) Municipal Hygiene: Sir Leslie Mackenzie, Member of the Scottish Board of Health. (4) Industrial Hygiene: President, Professor Sir Thomas Oliver. (5) Hygiene and Women's Work: President, Mrs. Mary Scharlieb. (6a) Bacteriology: President, Professor J. G. Adami, F.R.S., Vice-Chancellor of the University of Liverpool. (6b) Chemistry: President, Professor Benjamin Moore, F.R.S., Member of the Medical Research Committee.

During the Congress the Harben lectures of the institute will be delivered by Professor Maurice Nicolle, M.D., of the Pasteur Institute, Paris. An attractive programme of receptions, with visits to institutions of interest, and excursions to war centres and other places of note in Belgium, has been arranged, and delegates are being appointed by public health authorities. All interested in public health and national welfare questions may be admitted members of the Congress on application to the secretary. The arrangements for travelling and hotel accommodation are in the hands of Messrs. Thos. Cook and Son, Ludgate Circus, E.C., to whom application should be made.

A CENTRAL INSTITUTE FOR CHILD WELFARE.

A GREAT gift is announced in the sixth annual report of the Carnegie United Kingdom Trust, which has just appeared. The Central Council of Infant and Child Welfare, in which, through the efforts of Sir Arthur Stanley, chairman of the British Red Cross Society, eleven of the principal welfare societies in London are united, has qualified for the grant of £40,000 offered by the Carnegie Trustees for a central institute. Since the offer was originally made to the Council, the Red Cross Society has proposed to erect or purchase a large building to house (*a*) V.A.D. and Red Cross work; (*b*) a tuberculosis centre; (*c*) a college of nursing, besides the central welfare work; and the Carnegie Trustees have agreed to this proposal provided that a distinct wing is used for the child-welfare institute. No building has yet been acquired, but the Central Council has obtained temporary premises in which the work of the central institute is being commenced. Progress has been made in regard to a similar central institute in Edinburgh, but arrangements have not gone as far as in London. The report of the Carnegie Trust states that the policy of giving grants for Church organs is being discontinued, the trustees evidently being mindful of the injunction to them of the late founder: "Let my Trustees therefore ask themselves from time to time, from age to age, how they can best help man in his glorious ascent onward and upward, and to this end devote the fund."

THE UNIFICATION OF MEDICAL SERVICES IN RURAL AREAS.

IN his annual report for 1918 as county medical officer of health for Gloucestershire Dr. J. Middleton Martin summarises the scheme which has been adopted by that county council for the extension of medical services in the more rural districts. The venture has been referred to more than once in the medical press, and in view of its very practical bearing on the development of a unified service of medical treatment no excuse is necessary for re-sketching the outlines of the scheme. Almost every county with a considerable rural population has felt the difficulties and dangers involved in a possible multiplication of clinics, each for an individual purpose. In Gloucestershire the problem was made the more urgent by the quick succession of medical needs which came knocking at the county door for satisfaction—treatment of the tuberculous, of the venereal case, of the school child; the care of ex-Service men, and of mothers, infants, and young children. The county, after negotiations with the governing bodies of general and cottage hospitals and with other interested parties, has evolved a bold scheme for the provision of some 50 out-stations, or out-patient clinics. These will be somewhat on the lines of existing tuberculosis dispensaries, with consulting room, waiting room, and dressing rooms, and will be so distributed that one will be accessible within a radius of about three miles of every patient. At these clinics out-patient treatment will be available for all the special classes of persons for whom provision is now, or will in the future be, made out of the public purse. The usual medical attendants will be the local practitioners, assisted by the specialist staffs of the hospitals, while the specialist staffs of the county council, as regards tuberculosis and venereal disease, will also use the clinics for their particular work. The centres will be available for out-patient treatment under the Insurance Acts, while school cases will receive intermediate treatment by nurses, and ex-Service men by masseurs. The county council will provide and equip the clinics, which will, so far as possible, be in connexion with the cottage hospitals. The scheme will be controlled by a joint committee of the county council and of the general hospitals, and this committee will select the staffs for the various centres.

The growth and practical working of this scheme should be a matter of interest to the whole medical profession, and not least to the responsible officers of counties in which the same problem is becoming constantly more pressing. Those authorities who are slower in taking up the running will do well not to spoil the course for a later start by committing themselves meanwhile to bricks and mortar without very serious thought. The immediate moral appears to be, not to build premises for individual medical services if this can in any way be avoided. If premises cannot be rented, and building is after all found necessary, then it should be considered carefully whether the proposed site and type of building are such as will meet not only the immediate needs of the authority, but also the ultimate requirements of the neighbourhood; and, further, whether the site and the building are likely to commend themselves to the members of the medical profession who, it is to be hoped, will coöperate with the public authority in some such joint scheme as has been evolved in Gloucestershire.

MOTOR FUELS: MEDICAL AND PUBLIC CONSIDERATIONS.

THE report issued by the Board of Trade this week dealing with the costs, prices, and profits at all stages in respect of petrol, benzol, and other motor fuels obviously concerns the medical man. The report has been drawn up by a well-chosen subcommittee, and its conclusions call for very serious attention. At the outset it is shown that motor fuel is rapidly becoming of vital importance to practically every industry, not excluding agriculture, in all civilised countries. Therefore the concentration of control over the price and disposition of motor fuel in the hands of two enormously powerful capitalistic combines, practically world-wide in their scope, is regarded as constituting so dangerous a power, if it happens to be improperly used, that the governments of the world are asked imperatively to give attention to the situation. The demand for motor fuels tends to outstrip the world's present supply, and there is grave danger of a permanent famine in motor spirit, even at fabulous prices. We seem to be very slow in developing the possibilities of other fuels for use in motor service, and we are not surprised to find that the Committee is insistent that work should be begun at once to produce home or Empire fuel. Power alcohol, it concludes, is the only potentially unlimited source of supply, and it is urged that the Government should use every possible means to foster the production of power alcohol and should place no restriction on that production or the use of power alcohol in this country. Economic questions have also received careful attention, including the control of prices, and the views of the report here are eminently reasonable. The prohibition in regard to export of motor fuels is strongly recommended, and this applies particularly to benzol, and no motor spirit imported into this country should, in the opinion of the Committee, be allowed to be re-exported. The Committee asks that the findings of the report as to prices and export should be put into force forthwith. These conclusions will be received with satisfaction by the whole community, so important a place has motor fuel taken in the affairs of our daily life.

JOINT ILL IN FOALS.

AMONG other interesting matter the *Journal of Comparative Pathology and Therapeutics* for December, 1919, contains an account of experiments conducted at the Research Institute in Animal Pathology, Royal Veterinary College, London, into the cause and serum treatment of joint ill in foals. The investigations were conducted by Sir John McFadyean and Captain J. T. Edwards. The chief organisms found in bacterial and cultural examination of the diseased joints were streptococci, coliform bacilli, *Bacillus nephriditis* (Meyer), an interesting case of streptothrix, and three cases where the organisms were not of any named species. Seventy-two cases were examined during two years of research. The conclusion come to by the investigators is that vaccines and serums are not of any value in the treatment of pregnant mares who are likely to produce affected foals, nor are they preventive or curative of joint ill when applied to the foal itself. 253 cases were treated with the antistreptococcus serum and the authors base their conclusions on these results. Joint ill causes the death in early years of much valuable equine stock, and these investigations should lead to further understanding and research with regard to the disease. At present clean and hygienic stables, proper feeding of the dam, and careful attention to the umbilical cord of the foal at birth seem to be the best preventives. It is somewhat significant that common bred stock kept largely out of doors, or in stables with few animals in, suffer the least from outbreaks of joint ill.

DISABLED NURSES AND THEIR DEPENDANTS.

THE Special Grants Committee of the Ministry of Pensions has framed new regulations under which certain grants and allowances may be made in special cases to war disabled nurses and their dependants. These regulations, which take effect forthwith, apply to members of the Royal Naval Nursing Service and Reserve, Queen Alexandra's Imperial Nursing Service, the Army Nursing Service, the Territorial Force Nursing Service, and any other nursing service or reserve which is admissible under the Royal Warrant. The gist of the regulations is as follows:—

Nurses.—A supplementary or special allowance may be granted to a nurse where, in consequence of serious disablement arising from service during the war, she is unable to maintain herself in her pre-war standard of comfort, but the supplementary or special allowance together with any State pension which may be awarded shall not exceed £90 a year. In exceptional cases grants may be made to nurses to meet temporary distress or emergency. Recoverable advances may be made to nurses pending the receipt of moneys due, or which the Special Grants Committee considers may become due, from the State in respect of pension gratuity or other payment, provided that such advances shall only be made in cases of real necessity.

Dependants.—Where the parent, brother, or sister of a nurse is deprived by her death, in circumstances arising from service during the war, of any regular support which the parent, brother, or sister was receiving from the nurse before or during the war, or might reasonably have expected to receive from the nurse after the war, a supplementary or special allowance may be granted which, with any State pension which may have been awarded, shall not exceed the actual or prospective dependence and shall not exceed the total of £60 a year.

Children.—When a nurse, by reason of disablement arising from service during the war, is unable adequately to maintain her children, or where a nurse dies in consequence of war service, allowances for maintenance and education, not exceeding in amount those which may be paid under the Royal Warrant or the Special Grants Committee's Regulations for the maintenance and education of the children of a disabled or deceased officer, may be granted if the husband or widower of the nurse is deceased or if the Committee is satisfied that he cannot be expected to support the children.

Applications for allowances or grants should be headed "S.G.O." and addressed to the Secretary, Special Grants Committee, Officers' Branch, Millbank House, Westminster, S.W.1.

Sir Archibald Garrod has been appointed Regius Professor of Medicine at the University of Oxford.

THE Home Secretary has appointed Dr. William C. Sullivan, Superintendent of Rampton Criminal Lunatic Asylum, to the office of Superintendent of Broadmoor Asylum, vacant by the retirement of Sir John Baker.

AT Oxford, by a vote in Convocation of 434 to 359 on Tuesday last, Greek ceased to be a compulsory subject.

WE regret to record the death on March 2nd of Dr. Samuel West, consulting physician to St. Bartholomew's Hospital, the Royal Free Hospital, and King Edward VII. Sanatorium. His unremitting services as president of the Royal Medical Benevolent Fund will long be gratefully recalled by the less fortunate members of his profession.

WE note elsewhere the appointment of Dr. James McIntosh, Grocer's Company Research Scholar and Carnegie Fellow in Pathology, to the vacant Chair of Pathology at the Middlesex Hospital Medical School, and of Mr. Sidney Russ, D.Sc., to occupy the new Chair of Physics endowed by Messrs. S. B. and J. B. Joel. Last week the University of London acceded to the institution of a Chair of Radiology at the same school.

THE lectures and practical instruction for a diploma in Psychological Medicine at the Maudsley Hospital, Denmark Hill, having now been arranged, Sir Frederick Mott will be glad to meet medical officers of asylums and practitioners desirous of attending the course, on Wednesday, March 10th, at 2 P.M., at the hospital, in order to settle the days and hours to suit the convenience of the greatest number.

TUBERCULOSIS.

Government Attitude to the After-care of the Tuberculous.

IN a memorandum published in the *Times* of Feb. 2nd and signed, among many others, by Sir Clifford Allbutt and Dr. F. W. Burton-Fanning, it is pointed out that the recommendations of the Departmental Committee's report on tuberculous soldiers have not been acted on by the Government in respect of the third and most important recommendation. It appears that the Government has promised Treasury assistance with regard to the first two recommendations (increased capital grants to sanatoriums and training departments in colonies), but so far it has given no promise of financial assistance for permanent settlements. The Papworth authorities, for example, can get no Treasury help for their village settlement. The signatories of this memorandum urge the Government to promote the permanent village settlement, towards the costs of which the Committee recommended an outlay of a million pounds.

Establishment of a Farm Colony near Edinburgh.

At the annual general meeting of the contributors to the Royal Victoria Hospital Tuberculosis Trust Mr. Charles Cook, the chairman, pointed out that the growing tendency to regard tuberculosis as a problem of infant infection had led the Trust to plan their future operations with special reference (1) to the care and treatment of the manifestations of tuberculosis in whatever organ and at whatever age they occurred, and (2) to investigate and develop accredited lines of treatment of every form of tuberculosis. The application of these principles had resulted in the decision to establish a farm colony on national lines, to be available for the prolonged care and treatment of all forms of curable tuberculosis, precedence to be given to soldiers, sailors, war workers, and their relatives. The Trust's committee had selected Southfield, two miles from Edinburgh, for the purposes of a sanatorium, training colony, and school. The National Association for the Prevention of Tuberculosis had promised £4000 towards the purchase price of £9400, and £300 per annum for three years towards maintenance. With a little rearrangement accommodation could be provided for approximately 40 patients. Speaking at this meeting, Sir Arthur Stanley, chairman of the British Red Cross Society, discussed the larger outlook in the campaign against tuberculosis, and outlined a scheme for creating an international clearing house for ideas and experiences at Geneva, under the auspices of the Red Cross. He hoped that every country would be represented, and the fullest possible information be available as to the tuberculosis work in every part of the world.

A New Sanatorium for North Riding.

The North Riding County Council recently considered a recommendation of the public health committee with regard to the establishment at Morris Grange of a sanatorium with 155 beds. The estimated cost of this scheme was £70,000, exclusive of the water-supply, and the cost to the Riding would probably be about £42,000. The committee's scheme entailed a capital expenditure of £79,640, and an annual expenditure of £32,130. Pending the organisation of this scheme an interim scheme, involving a capital outlay of £1460 and an annual outlay of £5150, should be recommended. The discussion which took place resolved itself largely into a controversy as to the merits of sanatorium treatment in general. It was stated as the opinion of the greatest medical experts that "nothing was worse for consumptives than sanatorium treatment." Also that "the best medical opinion was in favour of sanatorium treatment." The committee's recommendations were adopted.

Tuberculosis in Portsmouth.

Dr. J. Fairley, chief tuberculosis officer and medical adviser to the Portsmouth Insurance Committee, has recently issued a report, dealing with the treatment of tuberculosis under the National Health Insurance Act in the Portsmouth area. In 1914 the total number of patients applying for treatment was 157. Of these only 32·5 per cent. could be traced as living. It was argued from these and other figures that sanatorium benefit was a failure, as judged by ultimate results. Dr. Fairley suggests that the segregation of infectious cases is the only way to control the disease. The Government should provide some half-dozen districts, each of about 20 square miles, where settlements could be established on a large scale. The scheme should first be voluntary, but should ultimately be administered with compulsory powers. Once admitted, a patient would remain till certified free from infection; then he could take his discharge if he wished to, but only on probation, and subject to periodic boarding. Families would be admitted conditionally, and the community would run itself, its local government, its marriage laws, its medical treatment, manufactures, and even trade unions. The community would be productive, though not entirely self-supporting.

Derbyshire's New Sanatorium.

At the quarterly meeting of the Derbyshire County Council the county medical officer of health reported on the proposal to acquire Bretby Hall as a sanatorium. The purchase price of the hall and outbuildings, with about 150 acres of land, and cottages thereon, would be £15,000, and the cost of adaptation £30,000. As £27,000, representing three-fifths of the total, would be paid by the Government, the balance charged to the tuberculosis account would be £18,000, and from this £9000 could be deducted as the Government's share of the outlay. The net capital cost to the county would, therefore, be only £9000.

Birmingham Inquiry into Sanatorium Treatment.

The results of sanatorium treatment in Birmingham are to be inquired into by a special committee, and a report will be presented to the Insurance Committee. It is realised in Birmingham that an important cause of failure in the administration of sanatorium benefit is the lack of provision for the dependents of insured persons undergoing treatment.

"The Harts," a house which stands in 20 acres at Woodford, Essex, has recently been purchased by the East Ham Council, and will be converted into a sanatorium with about 100 beds.

THE BRITISH INDUSTRIES FAIR.

THERE was truly a wealth of British-made goods on the spacious main floor of the Crystal Palace at the British Industries Fair held there from Feb. 23rd to March 5th under the auspices of the Board of Trade. The exhibition presented a most animated scene, and the support which it has received looks well for the future of British energy in many departments of trade and industry. Pottery and glass proved a beautiful demonstration, and impressive also was the display of scientific instruments, optical goods, spectacle ware, and photographic requisites. Many trades were admirably represented by their specimens of output—pianos, cutlery, toys, leather, book-binding, upholstery—all making for British industrial advance. The catalogue presented by the Board of Trade extended to no less than 611 pages. Many leading drug houses and surgical and scientific instrument makers were to the front. The stalls were for the most part artistically arranged. Of course, the primary object of the fair was business, and to bring into light the national power of effective productiveness. The medical visitor, however, must have found considerable interest in the things which concern his calling. We mention a few examples.

Drugs.

Messrs. Allen and Hanburys showed a good selection of their special products of "chrismol" for constipation and colloids, including "azoules," "kapsols," elixirs, and tablets. They made a prominent feature of preparations of internal secretions and other organo-therapeutic products, for example, of thyroid preparations, and especially of "polyglandin" preparations advocated in neurasthenia, melancholia, and sex neuroses, chronic toxæmia, and uterine disorders. Their neodiarsenol outfit for the preparation of injections of 914 (neosalvarsan) was on view.

Messrs. Burroughs, Wellcome, and Co. at their stand made a special feature of large samples of "kharsivan" and "neokharsivan" in addition to various "tabloid" products. Among other substances we may call attention to "iodicin" to replace with certain therapeutic advantages potassium iodide (3 to 9 gr. instead of potassium iodide 5 to 20 gr.). This firm also showed a range of tubes exhibiting the thyroid gland as taken from the sheep, its desiccation, powdering, and tabloid states.

The Standard Tablet Co., of Hove, showed a series of well-prepared medicaments of standard quality, including "thyroxine" tablets. Some prominence was given to the "marvellous" properties of the thyroid gland, owing, no doubt, to the sensational statements made in the press as to this substance proving to be a sort of elixir of life. (The misleading character of the deductions made in certain lay papers is elsewhere referred to.)

Messrs. Evans, Sons, Lescher, and Webb on their stand called special attention to the Liverpool virus for killing rats, and showed two rats as large as fat rabbits, one the bamboo rat of Malacca and the other a Brazilian species. The virus, it is claimed, is harmless to other domestic animals, and the rats must come into the open air to get water and to die. This firm also exhibited Evans's lysol in a prominent position.

Among other houses Messrs. Thomas Christy and Co. and Holt, Thompson, and Co., of Liverpool, had a good show of drugs and fine chemicals. The Western Dental Manufacturing Company had a fine display of dental requisites and appliances; and Messrs. Charles Salmon and Sons made a display of artificial limbs.

Scientific Instruments.

Scientific instruments were shown by Messrs. Baird and Tatlock, James Pitkin and Co., Negretti and Zambra, Newton and Wright, W. Watson and Sons, and Perken, Son, and Co., and Messrs. Raphaels, Ltd., made a special show of the "Maddox" near vision phorometer, invented by Dr. Maddox, of Bournemouth, as a standard test for muscular imbalances of the eye. Duroglass, Ltd. (selling agents, Baird and Tatlock), made a display of all kinds of chemical glassware, which they claimed was in every way equal to the German pre-war manufactures; and Messrs. Standley Belcher and Mason, Ltd., of Birmingham, offered a big show of British-made chemical apparatus respecting which they have issued an illustrated catalogue of 46 pages. They state that all their glassware is now made to conform to the verification tests of the National Physical Laboratory at Teddington. This laboratory was represented at a stall at which examples of standardisation of thermometers and scientific glass-measuring vessels could be inspected.

It seems likely enough that this well-organised and interesting collection of British manufactures will form the first of a series of annual events, for the executive state in the preface to the catalogue that this is known as the British Industries Fair and will *on this occasion* be held in the Crystal Palace. Recent events justify the scheme, and the support given must be gratifying to the authorities concerned, especially if they contemplate regular continuance of their activities.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Insanity and the War.

AT the annual meeting of the Royal Edinburgh Asylum, Morningside, the superintendent, Professor G. M. Robertson, referred to the effects of the war upon mental diseases. At the end of 1919 the total number of patients on the register was 993. During the year the admissions numbered 471. Alcoholic excess was believed to be the main cause of mental breakdown in about one-eighth of the male patients admitted, in spite of restrictions, high prices, and diluted alcohol. Among women the figure was only 1·2 per cent.—the lowest yet obtained. These figures, when compared with the numbers given by Sir Thomas Clouston in 1900 (1 in 3 in men and 14 per cent. in women), showed considerable improvement. The number of parochial patients admitted showed a great diminution. The war had been a cause of widespread anxiety. Although conscious of great relief, many had been surprised that they had experienced no sense of elation. The strain of the war lasted too long for a "rebound" to be enjoyed except by the young. Anxious emotion having accumulated and having lost its natural outlet in the war, now attached itself to anything else available, which then became the subject of over-anxious thoughts. We should be warned, said Professor Robertson, against pessimistic attitudes which had their origin in war. Others who had sustained bereavements during the war found these harder to bear now that the war was over, and many had sought solace in the study of spiritualism. Professor Robertson repeated his previous advice that it is dangerous for persons of neurotic temperament engaging in practical inquiries of a spiritualistic nature, adding that he did not consider Sir Conan Doyle or Sir Oliver Lodge safe judges, in view of their bereavements and unconscious desires. The phenomena in question occurred most frequently when there was disorganisation and dissociation of the mental functions. In toxic states, like delirium tremens, hallucinations of sight were easily aroused, and the patient was very open to suggestion. If, for example, such a patient were given a clean sheet of paper and told it was a letter from a friend he would sometimes start to read it, thus unconsciously providing his own news. Lameness and allied conditions, indigestion, and many other symptoms could result from a mental state, and be removable therefore through the action of the mind. One effect of the war experience was to create universal dissatisfaction with the legal and administrative arrangements for the care and treatment of the mentally afflicted. It emphasised also the need for the better provision of treatment for early cases. During the war thousands of soldiers received treatment for mental disorders without being certified lunatics, and similar facilities should obviously be accorded to civilians. It was believed that opportunity would be given to those who had the care of the insane to make suggestions in the recasting of the Lunacy Laws. The male nurses of the asylum had submitted a demand that female nurses should no longer be allowed to attend male patients, but he was of opinion that the employment of female nurses was beneficial to the male patients under their care.

Contravention of Venereal Diseases Act, 1917.

The trial took place in the High Court of Justiciary, Glasgow, on Feb. 24th, of a person styled "Professor" Eastburn, on a charge of contravening the Venereal Diseases Act, 1917. The "Professor's" fraudulent practice has on two occasions[1] been the subject of comment in your columns, where regret was expressed that no machinery apparently existed for his exposure and punishment. The case is of considerable interest as being the first tried in Scotland under the Act, and also for the light it throws upon the conduct and charges of unqualified practitioners. In the indictment there were 12 counts; objection to these was sustained in six, and the case proceeded upon the remainder. The accused pleaded not guilty. A seaman stated that he consulted him under the impression that he was a qualified medical man, and paid him a fee of £1. Accused undertook to cure him for £22, and for a further £34 to give him an additional course of treatment for nervousness. Another witness stated that he was charged £1 for consultation, and £50 for a course of treatment; this latter sum was paid by instalments, and after payment had been completed the "Professor" offered to give him another course of treatment for £38. In all he paid £88. Another stated that five or six years ago he was treated by Eastburn, and paid him between £40 and £50. Last September he again sought his advice because he was feeling run down. He was given pills "to build up his system," and told the course would last eight months. The medicine was said to be very expensive, and he was to be charged £265; this amount he paid in full. Similar evidence was given by other witnesses. The jury found the prisoner guilty on four of the counts, the verdict in the other two being "Not proven." Sentence of six months' imprisonment was passed, his lordship stating that he entirely agreed with the verdict, and that it was obvious that the accused contravened the Act for profit, well knowing its provisions, and that it was applicable to him.

[1] THE LANCET, 1901, i., 223; 1906, ii., 1413.

Effects of the War on the Incidence of Scabies.

At the annual meeting of the Edinburgh Dispensary for Diseases of the Skin Dr. Robert McLaren submitted some interesting figures showing that at present the incidence of scabies among the civilian population has greatly increased, and that it bears a direct relationship to the recent war. Amongst soldiers in the field diseases of the skin occupied a very important position as a cause of casualty; although not responsible for mortality, they accounted for a very large number of admissions to hospital. Although noted in previous wars, they had never before assumed such importance, which was doubtless due to the unusual conditions of trench warfare, and the enormous number of men constituting a modern army. The majority of the diseases were due to animal parasites, and the figures of the dispensary showed that the number of cases of scabies was exceptionally high, and that the increase bore a distinct relationship to the war period. Of all cases treated at the dispensary between 1911 and 1915 scabies accounted for from 8 to 10 per cent. In 1916 the percentage increased to 15·3; in 1917 to 18; and in 1918 to 31. For the year under review, 1919, the proportion had remained much the same, the actual figure being 30. The increase had therefore been coincident with the war years, and became progressively greater as the new armies entered the field. Without doubt the civil population was now suffering dermatologically from the war, and it was remarkable in how many instances patients could attribute the disease to infection from some soldier member of the family. One of the most important services which the dispensary could render to the community at present was to assist in reducing the number of cases, and in supplying free treatment to those whose circumstances required it.

March 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Winding-up of the Fund for the Assistance of Medical Men.

SINCE the beginning of the war a subscription list has been open among French medical men, and their foreign colleagues on war service in the country, for the establishment of a fund to help doctors and their families who have suffered hardships due to the war. Many doctors evacuated from the invaded regions and taking refuge behind the line have thus been helped, also the dependants of medical men on military duties, and their widows and children. The subscriptions amounted in all to 1,323,000 francs. Large contributions were sent from abroad by doctors who had studied in France, and by medical associations and learned societies in North and South America. The war having ended, the disposal of the accumulated funds has just been placed under consideration. Only 320,000 francs have been used so far; this sum may appear small for five years of war. Benevolent societies in France too often seem to work on the principle of making inadequate doles, and of being more proud of the large sums they have in the bank than of the number of people they have helped. In all, during the last three years the fund spent about 7000 francs a month. A total of 470 people have been helped, among them 120 widows, one of whom had 11 children; 45 of these are now to receive a regular pension; others have been given temporary help. On March 1st, 1919, 350 doctors were on the list, of whom 325 lived in the invaded districts. Since then the names of 50 other doctors have been added, making in all 400. The administrative council propose to divide the remaining million into three parts: 700,000 francs will be devoted to help doctors in the liberated regions, and 100,000 francs have been put in reserve for future applicants because, though the list officially closed on Feb. 28th, requests from late comers are still arriving. The remaining 200,000 francs will serve to continue as long as possible the monthly allowances to widows, orphans, and old and sick people. It is hoped that 7000 francs a month will be available for the next two and a half years. The sums allocated in each case vary with the position of the recipient. A student, son of a doctor, receives only his college fees or his board and lodging; a widow with children receives more. The fund has also bought instruments for doctors of the liberated regions, taking advantage of the sale of surplus goods by the Service de Santé Militaire.

Microbic Clouds and Barometric Variations.

Dr. Roux, director of the Pasteur Institute, presented to the Academy of Science, on behalf of M. Trillat, his latest researches on the influence exercised by a low barometric pressure on clouds of microbes artificially produced in a closed space. While slow attenuation has only a very feeble action, rapid lowering of pressure has the effect of producing an increase of weight and, in consequence, almost instantaneous precipitation of microbic droplets. M. Trillat explains this phenomenon by the rôle of the infinitely small particles which form the nuclei of condensation of the water vapour, under the influence of the rapid lowering of pressure and the instantaneous cooling which results therefrom. According to thermodynamic laws this condensation ought to take place the more easily when the bacteria are very small, such as *B. influenzæ*. When the atmosphere of inhabited places, especially in the neighbourhood of sick people, is in this condition the barometric depression presumably counts among the factors favourable to a high bacterial concentration in the air, and consequently to epidemic infections. To sum up, the variations of barometric pressure, in collecting microbes on the ground or in facilitating their suspension in the air, exerts an influence on the bacterial composition of the air.

Fly Destruction.

MM. Boyer and Guyot, in the *Bulletin of the Academy of Medicine*, have recommended a mixture of castor oil and syrup for this purpose. Flies are killed in a few seconds. The result is even quicker if two drops of croton oil are added to 30 gr. of castor oil.

March 2nd.

URBAN VITAL STATISTICS.

(Week ended Feb. 28th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 15·9, 17·4, and 16·8 in the three preceding weeks, rose to 17·7 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 18·5, or 0·6 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 7·8 in West Bromwich, 8·3 in Gillingham, and 8·9 in Hornsey, to 26·4 in Aberdare, 27·2 in Liverpool, and 28·3 in Barnsley. The principal epidemic diseases caused 446 deaths, which corresponded to an annual rate of 1·4 per 1000, and comprised 184 from measles, 111 from whooping-cough, 72 from diphtheria, 61 from infantile diarrhœa, 11 from scarlet fever, and 7 from enteric fever. Measles caused a death-rate of 1·9 in Wigan, 2·0 in Barrow-in-Furness, 2·2 in Nottingham, 3·1 in Liverpool, and 5·4 in Barnsley; whooping-cough of 1·3 in Leeds, 1·4 in Southampton, and 1·8 in Rochdale; and diphtheria of 2·1 in Merthyr Tydfil. The deaths from influenza, which had increased from 66 to 161 in the four preceding weeks, further rose to 178, and included 38 in London, 25 in Birmingham, 19 in Liverpool, 12 in Leeds, and 6 each in Manchester and Hull. There were 2316 cases of scarlet fever, 2026 of diphtheria, and 4 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2415, 2000, and 2 respectively at the end of the previous week. The causes of 40 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham, 4 each in London and Liverpool, and 3 each in Leicester and Sunderland.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at 2,400,000 persons, the annual rate of mortality, which had been 14·7, 14·7, and 14·2 in the three preceding weeks, rose to 15·7 per 1000. The 316 deaths in Glasgow corresponded to an annual rate of 14·8 per 1000, and included 5 each from diphtheria and infantile diarrhœa, 3 from measles, and 2 from whooping-cough. The 93 deaths in Edinburgh were equal to a rate of 14·2 per 1000, and included 3 from diphtheria, 2 from measles, and 1 from scarlet fever.

Irish Towns.—The 174 deaths in Dublin corresponded to an annual rate of 21·9, or 5·4 per 1000 above that recorded in the previous week, and included 3 each from whooping-cough, diphtheria, and infantile diarrhœa, and 1 from measles. The 173 deaths in Belfast were equal to a rate of 21·8 per 1000, and included 4 from scarlet fever, 3 from whooping-cough, 2 from measles, and 1 each from enteric fever, diphtheria, and infantile diarrhœa.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lieut-Col. L. Addams-Williams retires on retired pay.

Major and Bt. Lieut.-Col. R. A. Bryden relinquishes the temporary rank of Lieutenant-Colonel on ceasing to command a Medical Unit.

Major H. C. Sidgwick relinquishes the acting rank of Lieutenant-Colonel.

Major V. G. Johnson is placed temporarily on the half-pay list on account of ill-health.

Temp. Major J. C. Davies (Major, 4th R.W. Fus., T.F.) relinquishes his temporary commission on ceasing to be employed with the Field Ambulances of the 43rd Division.

C. S. Stolterfoth and S. F. Cheesman, late temporary Captains, to be temporary Captain.

Officers relinquishing their commissions:—Temporary Captains granted the rank of Major: H. H. Hepburn, H. H. Dunmere, B. Knowles, J. A. Paterson. Temporary Captains retaining the rank of Captain: C. D. Walker, L. R. Pickett, A. F. Palmer, W. J. Moloney, F. J. Pierce, E. W. Hall, L. J. O'Donovan, S. E. Holder, L. Gameson, M. Dobbs, D. H. Vickery, J. F. Wolfe, T. F. Shackleton, J. L. Smith, W. H. Stott, J. Scott, F. E. McGee, E. G. D. Milsom, G. M. Elliott, J. S. Byrne, E. H. Eastwood, N. Elrington. Temp. Lieut. D. I. McNaughton (retains the rank of Lieutenant).

SPECIAL RESERVE OF OFFICERS.

Captains relinquishing their commissions:—D. C. Macdonald (granted the rank of Major), W. A. Hawes (retains the rank of Captain).

TERRITORIAL FORCE.

1st Southern General Hospital: Lieut.-Col. F. W. Ellis is restored to the establishment.

ROYAL AIR FORCE.

Medical Branch.—Lieut. A. G. Hewer to be Captain.

DEATHS IN THE SERVICES.

Lieut.-Col. John Henry Connel Whipple, Brigade Surgeon, A.M.S., retired, whose death in London on Feb. 20th is announced, was born on Dec. 31st, 1840. Entering St. George's Hospital in 1858, he was a contemporary of the late Mr. Pickering Pick and Dr. George Bernard Brodie. Col. Whipple took the M.R.C.S. Eng. in 1863 and the M.D. St. Andrews in 1862. He entered the Army Medical Service as assistant surgeon, staff, Sept. 30th, 1864; was appointed to the 21st Foot, May 16th, 1865; to the Coldstream Guards, Oct. 14th, 1868. His designation was altered to surgeon under Royal Warrant, March 1st, 1873. He was promoted surgeon-major, Grenadier Guardians, June 21st, 1885, and he retired from the Service with the rank of brigade-surgeon, August 19th, 1885. His designation of surgeon-major was altered to surgeon-lieutenant-colonel, Sept. 30th, 1894, under *London Gazette* notification of Oct. 17th, 1893. He served in Egypt, 1882, being present at Tel-el-Mahuta and Tel-el-Kebir, for which he had the medal with clasp and the Khedive's Star.

SPECIAL NEUROLOGICAL BOARD: PRESENTATION TO DR. W. A. BREND.—At a dinner held in the Great Central Hotel on Feb. 28th, Dr. Muirhead Martin in the chair, Dr. W. A. Brend was the recipient of a presentation consisting of an inscribed album, a silver rose-bowl, and a complete edition of Pepys's Diary, from over 60 past and present members of the Special Neurological Board and Clinic, Lancaster Gate. In making the presentation the chairman expressed the personal regard of the staff for Dr. Brend and their admiration of his work during the term of his presidency of the Board, now brought to a close by his appointment as Neurological D.C.M.S. for the London region. Dr. Brend, in reply, referred to the difficulties overcome before the Board attained its present influential position, and commented on the growing importance of its treatment branch and clinic in the development of psychotherapy. Dr. H. E. Davison, who succeeds to the post of President, was also a guest, and the other speakers were Drs. Charlton Briscoe, P. Bousfield, Danvers-Atkinson, Duncan, David Forsyth, Laing Gordon, and Travers-Smith. Mr. Cortlandt MacMahon with song, and Dr. Bowen with legerdemain, contributed to the programme of the entertainment.

Correspondence.

"Audi alteram partem."

THE MACKENZIE DAVIDSON MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—In surveying the devastation of five years of war, the nation is beginning to realise that some compensation may be found in the great stimulus which science has received. In no branch of science has this been more marked than in the field of radiology. In the diagnosis of disease and in the localisation of foreign bodies and bone injuries, radiology has played a vital part in the war and has given invaluable aid to the thousands of medical officers serving in the Forces. Remarkable as has been the development of radiology during the war, there is need for watchfulness lest full advantage be not taken of this stimulus and a period of reaction set in. There is pressing need of unremitting research. For this is required the provision of the best equipment possible, and also a more thorough and systematic scheme of teaching. The University of Cambridge is alive to these requirements, and a diploma in radiology and electrology at the University has been established. It is felt that the success of the step will be greatly assured if similar facilities are provided in London.

The death of Sir James Mackenzie Davidson in the prime of life has deprived radiology of one of its most distinguished exponents, whose name is specially associated with the development of radiographic technique, and particularly that of stereoscopic radiography, and with the introduction in this country of the method of the localisation of foreign bodies to which so many thousands of wounded men owe a deep debt of gratitude. Mackenzie Davidson's reputation was international. In this country he was rightly regarded as the head of his profession, and throughout his career he was unsparing in his efforts to raise the status of radiology among the sciences. He was especially insistent on the fundamental value of physics to radiology, particularly in regard to methods of measurement and the designing of equipment, subjects in which he was deeply interested up to the time of his death. Many in his own branch of the profession and a number of his friends and former patients, wishing to keep his memory green, have suggested that an appeal for funds should be made to found a Mackenzie Davidson Chair of Radiology at some University. Had Mackenzie Davidson lived he would have been among the first actively and generously to support the foundation of an institute for teaching and research in radiology, of which he was one of the earliest pioneers. If funds permit, it is hoped to found such an institute, to which possibly the chair could be attached, and of which the personnel and equipment would be beyond reproach. The benefit accruing to the British School of Radiology would be incalculable.

Till quite recently radiology has been regarded as a purely medical subject, but experimental research has shown that X rays may be profitably employed commercially in a number of industries. A new subject, radiometallography, has, for example, come into being, which offers great possibilities for examining the internal structure of metals and other materials. In this connexion radiology has already been turned to account by the steel manufacturer, the metallurgist, the engineer, the manufacturer of explosives, the aircraft constructor, the glass manufacturer, &c. The future of radiology will therefore lie, not only in the fight against disease and suffering, but also in the increase of commercial and industrial efficiency. But these new branches of radiology need much investigatory work before they can come fully into their own, and a Chair of Radiology associated with an X ray Institute should play a worthy part in such development.

It is in the belief that the scientific study and teaching of radiology will materially add to the well-being of the human race that the Committee venture to put forward this appeal for public support. Cheques should be made payable to the London Joint City and Midland Bank, crossed "& Co." and marked "The Mackenzie Davidson Memorial Fund," and sent to Dr. Robert Knox, 38, Harley-street, W. 1.

We are, Sir, yours faithfully,

BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 21st is an annotation referring to blind masseurs. In the concluding paragraph thereof the opinion is expressed that a blinded masseur is incapable of giving effective remedial exercise and re-education treatment. To this opinion I wish to take very strong exception.

Considerable experience of blinded masseurs, who have also been trained to apply remedial exercises and to re-educate muscles, has convinced me that with careful and adequate preparation there is no reason whatever why a blind masseur or masseuse should not be able to apply any of the remedial exercises described by Kleen, Wide, or any other disciple of Ling (I write as one who was trained in this method of treatment in Stockholm). As a further proof, I may mention the fact that a member of the Association of Certificated Blind Masseurs passed the *full* examination conducted by the Incorporated Society of Trained Masseuses, qualifying for the certificate in "Swedish remedial exercises," and came out *first* in the list, although he was the only blind examinee! I consider that the paragraph referred to is calculated to affect adversely the prospects of a very deserving, enthusiastic, and capable band of workers, worthy of every possible help and fair treatment. I disagree entirely with the statement that "the blind administrator will be tempted to mete out to patients inferior treatment."

I state with conviction that if a blind masseur has been properly trained his treatment will *not* be inferior to that of an administrator gifted with sight.

I am, Sir, yours faithfully,
W. H. BROAD, M.D., Major, R.A.M.C.,
Lately O.I.C., Physical Treatment Department, Alder Hey Military Hospital.
Liverpool, Feb. 25th, 1920.

To the Editor of THE LANCET.

SIR,—Many thanks for your generous reference to the Association of Certificated Blind Masseurs in your issue of Feb. 21st. In regard to the final paragraph our men go through a specially prepared course of remedial exercises, but I quite agree with you that perfection in these is out of the reach of the blind practitioner.

I am, Sir, yours faithfully,
ARTHUR PEARSON,
Chairman, Blinded Soldiers' and Sailors' Care Committee.
Feb. 26th, 1920.

A PROFESSOR OF MILITARY MEDICAL HISTORY FOR OUR INDIAN WARS.

To the Editor of THE LANCET.

SIR,—A letter from Major-General Sir G. J. H. Evatt, A.M.S., in your issue of Jan. 31st, contains the valuable suggestion that a medical history of our Indian wars should be compiled. I am in entire agreement with him in this, as I have from time to time during the last quarter of a century experienced the greatest difficulty in collecting data on the subject. The same suggestion was put forward in my "Prevention of Disease and Inefficiency, with Special Reference to Indian Frontier Warfare," second edition, 1911. The records from which such a history could be compiled are scattered in a host of files in various departments in Simla and in the old files stored in Calcutta. Some useful information on the subject is also to be found in that delightful and charmingly written work, "History of the Indian Medical Service," two volumes, by Lieutenant-Colonel D. G. Crawford, I.M.S. (Thacker, Spink, and Co., Calcutta). For the compilation of such a history I would suggest that a senior major or junior lieutenant-colonel of the I.M.S. with a talent for collecting and arranging historical facts be selected, and placed on special duty for the purpose for six months.

I do not see my way to agreeing with General Evatt's further suggestion that "Military Medical History for our Indian Wars" should be made the subject of a professorship. I greatly doubt if the material available would be sufficiently entensive to justify this. It could, however, be most profitably included in some other professorship such as one dealing with medical organisation and administration in the field.

One earnestly hopes that in the near future a military medical school will be opened in India and that the matter under reference will receive due consideration in connexion with it.

I am, Sir, yours faithfully,
P. HEHIR,
Major-General, I.M.S.
London, March 1st, 1920.

ARTIFICIAL SPIROCHÆTES.

To the Editor of THE LANCET.

SIR,—It may interest those who have been concerned in recent years with the motile "streamers" which exude from red blood corpuscles and pretend they are spirochætes to know of an excellent description of them given by Dr. William Addison in the Transactions of the Microscopical Society of London, Vol. IX., 1861, p. 22, and Plate III. (in the *Quarterly Journal of Microscopical Science*, n.s., Vol. I.). His recipe for their production is to mix equal quantities of blood and a solution containing 1 gr. of common salt and ½ gr. of bicarbonate of soda in two fluid drachms of water added to half a fluid ounce of good sherry wine. Port wine containing a grain of sulphate of quinine in half a fluid ounce was also efficacious; so was a mixture of one part of fresh urine with two or three parts of sherry wine.

I am, Sir, yours faithfully,
A. E. BOYCOTT.
Radlett, Feb. 28th, 1920.

THE NEEDS OF AUSTRIAN MEDICAL FAMILIES.

To the Editor of THE LANCET.

SIR,—May I make an appeal through your columns for the families of physicians in Vienna, especially the lecturers in the University, who are not in private practice and are in dire distress? I have been aiding a number of friends and acquaintances for some time and have received to-day a letter from an eminent university professor, who is well known in England, in which he says: "Whatever you may have heard or read about our condition is far from exaggerated, but rather underestimates the state of our misery. The exchange alone (the English sovereign being formerly 24 crowns and now 950) is an indication of our extreme poverty. We hunger and freeze—for six weeks I have seen no coal—and it is a wonder that I can sometimes summon energy for work. Indeed, there is a danger of falling into a state of complete lethargy. ...... Being father of a family I venture to make use of your kind offer. If you could send us corned beef, flour, fat, and condensed milk, you would do us a great service."

Much is, no doubt, being done in England and elsewhere for the very poor of Vienna; but, Sir, let us not forget our own colleagues, some of them famous and too proud to disclose their misery. THE LANCET has been so often the leader in appeals for charity, and is so well known in Vienna, that I beg you will again take the initiative in an appeal to British medical men to help their colleagues in Vienna; and no doubt you know better than I do how to convey food in larger quantities over there and how to organise its distribution by some accredited representative.

May I add, since clothes cannot be bought in Vienna (a suit costing 20,000 crowns), that old garments in good condition might be sent as well, and that a present might be made of the more important new books and journals, for, as my correspondent writes: "I cannot buy any books now—English books will perhaps never more be attainable; to buy my own work would cost a fortune now."—I am, Sir, yours faithfully,

BERNARD HOLLANDER.

57, Wimpole-street, W., March 1st, 1920.

⁂ The distribution may safely be left in the hands of the Friends' Emergency and War Victims' Relief Committee (Hon. Sec., Miss A. Ruth Fry, 27, Chancery-lane, London, W.C. 2), which has a centre in Vienna, and finds itself at this moment seriously handicapped by lack of funds. In face of the present desperate situation this Committee is unable to continue its purchases of much-needed fats, milks, and other foods. Every report that reaches the Relief Committee serves but to confirm the impression that unless Austria, Poland, and Germany are speedily helped they will become victims of disease and famine likely to menace the whole life of Europe.—ED. L.

THE THERAPEUTIC USES OF OXYGEN.

To the Editor of THE LANCET.

SIR,—The discussion at the Royal Society of Medicine on the therapeutic use of oxygen, as reported in your columns of Feb. 7th, encourages me to put on record some observations I have made at different periods. As no exact apparatus was at my disposal, they must be looked upon in the light of clinical notes. First, many years ago my only source of supply was chlorate of potash and dioxide of manganese. This oxygen, of course, contained a trace of chlorine; in fact, its valuable properties were, as far as I was able to observe, largely dependent on that contamination. The effects of inhalation were hypnotic and stimulant. The latter quality was recognised in heart failure and during critical periods of disease, when this oxygen proved superior to alcohol, strychnine, or any of the ordinary stimulants. This "chlorine oxygen" also proved to be a hypnotic of considerable power, valuable in irritable heart with insufficient aeration. It was sufficiently powerful to make the attendant find it difficult to keep awake in such an atmosphere. The character of the sleep thus induced was peculiarly refreshing, similar to that obtained by driving in the open air. But this form of oxygen administration entailed two disadvantages: it leaves the mouth excessively dry and it discolours all the brasswork in the room.

The next time I took up the question with ordinary cylinder oxygen, which I call "dead oxygen," as it appeared to me to possess no other therapeutic value than the replacing the atmospheric and pulmonary deficiency. In the light of the discussion this was an error. Its greatest value in my hands was in certain cases of pneumonia, where the discoloration and dyspnœa were out of proportion to the other symptoms. For the practitioner away from the metropolis the form was convenient for administration during chloroform anæsthesia, conveyed through a tube under the mask.

The third variety of oxygen I experimented with therapeutically was obtained by dropping water on sodox, a form of dioxide of sodium. The result of administering oxygen in this form was a remarkable increase of metabolic action. "Sodium oxygen" is sufficiently active to necessitate careful regulation of the dose, and I found the best period of administration varied from two to 15 minutes. Advantage was derived by those cases in which improved metabolism was required, but in whom there was no deficiency in the elimination of waste products. If elimination was at fault the result was liable to prove injurious, by increasing the strain on excretory organisms already over-taxed. In sanatorium treatment of phthisis it proved of benefit in rendering the muscles more resilient and improving metabolic well-being. Latterly, those returning to work were put on five minutes' inhalation twice daily after meals. In hypersensitive cases and advanced phthisis inhalation proved deleterious, and in a few cases dangerous, producing depression and collapse.

Sodium oxygen is evidently more active than the other forms of oxygen, and will, I believe, be found to be a therapeutic agent of no mean order.

I am, Sir, yours faithfully,

Middlesbrough, Feb. 21st, 1920. HENRY A. ELLIS.

THE LATE COLONEL D. F. KEEGAN, I.M.S.

To the Editor of THE LANCET.

SIR,—The death of Colonel Keegan, reported a few days ago, removes one of the grandest figures in the history of the Indian Medical Service. If you named the three biggest surgeons which the Indian Medical Service has produced you must include the name of Keegan. The work he did will live for generations yet unborn, and he will be more honoured in his urn than he was when alive. This is the fate of all pioneers. Death removes them from the field of jealousy. When he was doing the spadework he had to fight the world, and he did it and established his case. We are all familiar with the work Keegan did in rhinoplasty and how he established the Indian operation as *the* operation for all time.

Keegan was a man with a fine imagination, a powerful and versatile intellect, and a strong character. He was a powerful, clear, and incisive though courteous controversialist. It is only a very able man in any public service who can go his own way and live as an official. Keegan did this. As a man he was one of the most kindhearted, the most generous, and the most genial of men. As a friend he was one of the few capable of that genuine friendship, as distinguished from fair-weather friendship, who would life itself resign at the sacred call of friendship. There was no self-interested trimming of wings for the weather about Keegan.

He did most of his service in Central India, where his fine personality was a political influence of the first magnitude. He died at the age of 80 years. The Government of India did not do themselves the honour of honouring him with a decoration. A man like Keegan does not require a decoration as his passport. He made no pretension to be what in popular language is called an "aristocrat." He belonged to a much higher order. He was an aristocrat of the moral code of the New Testament. He leaves a heritage to his son and his two daughters which "moths and rust do not corrupt, nor thieves break through nor steal."

I am, Sir, yours faithfully,

H. SMITH,

Amritsur, Jan. 31st, 1920. Lieutenant-Colonel, I.M.S.

PARA-SCARLET AND DENGUE FEVERS.

To the Editor of THE LANCET.

SIR,—In connexion with the correspondence in your columns on the question of para-scarlet fever perhaps the following case may be of interest. On Dec. 30th last I was called to see J. D., aged 14 years. She had taken ill the previous evening with headache—temperature 101° F. No vomiting or throat symptoms, but slight injection of the fauces. Headache persisted at intervals, and the temperature rose with morning remissions to 103·6°. The pulse did not exceed 108. On the evening of the second day there was slight evidence of a rash appearing on the back, pharyngitis, and the glands in the posterior triangle of the neck were enlarged. On the morning of the third day the rash had spread widely but never involved the front and upper portion of the chest. The rash was suspiciously like that of scarlet fever but for lack of uniformity, while small selected areas had the appearance of measles. The tongue was coated with a thick fur, but at no time could it be said to resemble the white or red strawberry.

There was marked hyperæmia of the nasal and pharyngeal mucous membranes, and epistaxis was repeated and troublesome. Headache and sleeplessness were the other chief features. The rash disappeared slowly, and on its disappearance fleeting pains in the joints were manifest. There was no albuminuria throughout. For ten days after the temperature had subsided there was a distinct feeling of malaise; then occurred a terminal rise with complete recovery. Four weeks from the date of onset desquamation was taking place on the palms of the hands. The only possible source of infection was a visit to the dentist, and recently it has transpired that he took to bed with a sharp attack of dengue fever immediately after J. D.'s visit.

I am, Sir, yours faithfully,

Khanka, Cairo, Feb. 16th, 1920. R. S. MILLER, M.D.

THE NOMENCLATURE OF TRYPANOSOMES: A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my letter, as published in your issue of Feb. 21st, the word "*Trypocastellanelleæ*" is made to appear a little longer than it actually is; an additional "*an*" has crept into it inadvertently and in the wrong place. I remember that I found the word somewhat difficult to type, and I can only express my regret if I overlooked the mistake in the proof. The word is printed correctly, however, in the paragraph dealing particularly with it.

I will take this opportunity of adding that I hope it was quite clear that my letter was not intended as an argument either in favour of, or against, the actual classificatory changes proposed—whether generic or specific. My only object was to protest against a growing tendency to (as I regard it) travesty scientific nomenclature in connexion with the protozoa. Personally, I would much prefer to continue to call such well-known parasites as *Trypanosoma lewisi* and *T. gambiense* by these names than to have to think of them as *Lewisonella lewisi* and *Castellanella castellanii* respectively. It may be noted that Professor Minchin, although he recognised that *Babesia* was most probably the correct name, preferred to use *Piroplasma*, and in his book he put the latter name first in his account of this genus (p. 379). If *Babesia* has to stand, the result is, that of all the types into which this important group has been subdivided there is only the doubtful "*Anaplasma*" whose generic name gives us any idea of what kind of creature is concerned! Is not this an absurdity to be avoided in the future?

I am, Sir, yours faithfully,

Feb. 26th, 1920. H. M. WOODCOCK.

*** The error was in the original manuscript and remained uncorrected in the proof, an oversight committed as much by ourselves as by the author.—ED. L.

DEATH OF MR. C. GORDON HEWITT.—The death is announced of Charles Gordon Hewitt, D.Sc., F.R.S.C., Dominion Entomologist in Canada, and formerly lecturer in economic zoology in the University of Manchester. Mr. Hewitt was a recognised authority on the relation of houseflies to disease, his papers on this subject appearing in a book entitled "The House-Fly," published at the Cambridge University Press in 1914. During the war leaflets from his pen on the suppression of insects affecting troops were issued by the Canadian Department of Agriculture. His intimate entomological knowledge was placed freely at the service of humanity.

LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES.—The annual meeting of this hospital was held in the Town Hall on Feb. 27th. The report showed that the number of attendances recorded—37,610—was an increase of 7395 on the figures of the previous year. The average daily number of beds occupied by in-patients was 19 as compared with 14. Unfortunately the finances have not increased in a corresponding ratio, and the bank overdraft now stands at close on £4000. Like all other voluntary hospitals, this institution is suffering from the uncertainty which prevails as to the future of the voluntary principle. The Lord Mayor, who presided, expressed the hope that when the handsome sum, subscribed through the appeal of the late Lord Mayor, came to be divided, the strain on this hospital's funds would be considerably relieved.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Awards for Medical Discoveries.

A DEPUTATION from the Medical Committee of the House of Commons was received by Mr. BALFOUR (Lord President of the Council) on Tuesday, March 2nd, to urge upon the Government the establishment of a scheme of awards for medical and scientific discoveries. The suggestion put forward by the deputation was that £20,000 a year should be devoted to giving awards on similar lines to the Nobel prizes. Mr. BALFOUR received the proposal sympathetically, but pointed out that the settlement of who had actually made a particular discovery might be a difficult matter. In his view a better plan would be to place investigators in a more comfortable position for carrying out their research work.

The New Insurance Bill.

Although the text of the new National Health Insurance Bill has not yet been published, it is understood that the measure does not alter the general scope of medical benefit. Regulations, however, will follow as a result of it which will involve considerable modifications, the object of which is to improve the standard of medical services in connexion with insurance and to simplify its administration. Under the new regulations a limit is to be placed on the number of patients for whom a doctor can be responsible single-handed. A national maximum of 3000 has been fixed. The scope of free choice of doctor is to be enlarged, and there will be a half-yearly choice instead of a yearly choice. Obligations are to be laid on medical men to give emergency treatment and to provide proper surgery and waiting-room accommodation.

HOUSE OF COMMONS.

TUESDAY, FEB. 24TH.

Morphia, Morphia Salts, and Opium.

Mr. GILBERT asked the Parliamentary Secretary of the Board of Trade what was the total amount of morphia of British manufacture exported in the year 1919; what amount was exported to Japan and the United States respectively; whether the amounts included consignments by post; and what amount of opium was imported from India, Persia, and Turkey respectively into Great Britain during the year 1919.—Mr. BRIDGEMAN replied: The quantity of morphia and morphia salts registered as exported from the United Kingdom in the year 1919 was 322,970 oz., of which 121,474 oz. went to the United States of America. The records show that no morphia and morphia salts were exported to Japan. No particulars are available with regard to consignments by post. The quantities of opium registered as imported into the United Kingdom during the year 1919 from British India, Persia, and Turkey respectively were as follows: British India, 466,475 lb.; Persia, 30,558 lb.; European Turkey, 204,966 lb.; Asiatic Turkey, 133,157 lb.

Arsenical Treatment of Syphilis.

Mr. WATERSON asked the Minister of Health whether his attention had been drawn to the particulars as to a large number of deaths of soldiers after arsenical treatment for syphilis given in the paper read by Brevet-Colonel L. W. Harrison at a meeting of the British Medical Association in April, 1919; whether any special inquiries had been made into the cause of the deaths in question; and, if so, whether it was proposed to publish the results of the inquiries.—Dr. ADDISON replied: The answer to the first part of the question is in the affirmative. A special committee appointed by the Medical Research Committee is inquiring inter alia into the toxic effects of arsenobenzol compounds, and I understand that the report of the Committee will be published in due course.

Mr. WATERSON asked the Minister of Health whether he had obtained a copy of the report of the commission which sat in Germany to inquire into the cause of toxic effects produced by the arsenical treatment of syphilis; and, if so, would he arrange for a translation or a résumé of it to be published.—Dr. ADDISON replied: I have taken steps to procure the report in question, and when I have received it I will consider what I can do to meet the request of the honourable Member.

Medical Officer's Demobilisation.

Mr. ROYCE asked the Secretary of State for War whether a cable was sent to Mesopotamia in May last ordering the demobilisation of Captain R. Gillespie Smith, Royal Army Medical Corps; and, if so, why was the order not carried out, and could he state if this officer was still in Mesopotamia.—Mr. CHURCHILL replied: The answer to the first part of the question is in the negative. A cablegram was, however, sent to the General Officer Commanding-in-Chief, Mesopotamia, asking that Captain Gillespie Smith should be sent home as soon as his services could be spared. According to the latest information in the Department he is still serving in Mesopotamia.

WEDNESDAY, FEB. 25TH.

Promotion in the Naval Medical Service.

Sir Watson Cheyne asked the First Lord of the Admiralty if he was aware that the proportion of surgeon captains to surgeon commanders was 1 to 19, of paymaster captains to paymaster commanders 1 to 11, of engineer captains to engineer commanders 1 to 9½, and of executive captains to executive commanders 5 to 9; whether he realised that this point was a serious matter for the Naval Medical Service, and might markedly increase the difficulty of recruiting for that service; whether any steps were being taken to remedy this disparity between the various branches of the service, and at least to place the surgeon captains on the same basis as the paymaster and engineer captains, and if so, when the result would be announced.—Dr. Macnamara (Parliamentary Secretary to the Admiralty) replied: The proportions are approximately as stated, though the proportion of surgeon captains to surgeon commanders is more correctly 1 to 17·4. At the present time, however, there is a considerable surplus in the number of surgeon commanders and a shortage in the junior ranks, so that normally the proportion of surgeon commanders would be very much less. The question of the number of higher ranks in the Naval Medical Service has been under consideration, and it has been decided to increase the number of surgeon rear-admirals to six and the number of surgeon captains to 16, excluding one officer specially promoted to that rank for services during the war. The number will be further considered as necessity arises, dependent in all cases on the requirements of the Naval Service. It may be pointed out that the conditions of service of medical officers in the Royal Navy have been very appreciably improved as a result of the recommendations of the Jerram-Halsey Committee, for not only have the rates of pay been increased, but the period of service for promotion from surgeon lieutenant to surgeon lieutenant-commander has been reduced from eight years to six years, and similarly that for promotion from surgeon lieutenant commander to surgeon commander, a reduction of four years in all. The earlier advancement to surgeon commander, thus authorised, has increase the apparent disparity of numbers in the higher ranks.

Deaths at Chinley Isolation Hospital.

Mr. Robert Young asked the Minister of Health if he was aware that the death-rate at the Chinley Isolation Hospital was 55 per cent. during the period Nov. 24th to 29th, 1919; what was the reason why this high death-rate took place; whether three boys, aged 9, 7, and 5 years respectively, died within the dates referred to, all members of the same family, after antitoxin treatment; whether the cause of these deaths had been investigated, and the antitoxin in use at the time stated impounded for analysis as to its purity and with what result; whether two of the cases referred to were out of bed one hour before death; and whether the third case, admitted for observation only, died from an overdose of antitoxin.—Dr. Addison replied: I am informed that during the periods mentioned the number of patients in the Chinley Isolation Hospital was 24, of whom 12 were cases of diphtheria, and that during the same period the number of deaths in the hospital was four, in each case from diphtheria. These fatal cases included the three boys referred to by the honourable Member. The facts as to these cases, together with the local incidence of diphtheria in the neighbourhood, have been fully investigated by one of the medical officers, as well as by the county and local medical officers. They are of opinion that the high mortality was due to the malignant character of the disease and to the fact that those in charge of the cases before admission to the hospital had failed to administer diphtheria antitoxin. When the cases were admitted to hospital they were all in an advanced stage of the disease; and although antitoxin was at once administered it was then too late to stay the progress of the disease. I am satisfied on the evidence that the administration of antitoxin was in no way prejudicial or related to the fatal result, and that the treatment given to the cases after admission to hospital was in all respects adequate.

Hospitality for Starving Children from Central Europe.

Colonel Burn asked the Minister of Health if he was aware that the Bradford council had rejected the motion for extending hospitality to the starving children of Central Europe; and what steps did he intend to take in the event of other towns in this country expressing willingness to receive alien children from the countries of our late enemies; (2) whether any consideration had been given to this proposal from the point of view of the public health and possible contagion.

Lieutenant-Commander Kenworthy: May I, before the question is answered, ask the right honourable gentleman whether the official religion of this country is still Christianity?

Dr. Addison replied: That has nothing to do with my answer. With regard to the Bradford council, I have no information to the effect suggested in the question. Proposals of the kind referred to by the honourable Member have been brought to the attention of the Government and have been discussed between the Foreign Office, the Home Office, and the Ministry of Health. The necessity of safeguarding the health of the people in this country in the event of any such proposals being sanctioned and carried out has been very closely considered and the requisite steps thought out.

Colonel Burn: Does not my right honourable friend think it inadvisable that the children of enemy aliens should be brought to this country, and does he not think that any money required for their assistance should be spent or disbursed in their own country?—Dr. Addison: I cannot say as to that. I have to consider whether adequate steps are taken to safeguard the health of the community, and that I have done.

Mr. Ratcliffe: Is the right honourable gentleman aware that the Bradford corporation, whilst refusing to accept 1000 children to be domiciled in Bradford, voted £1000 and opened a public subscription to be sent for the relief of the children in the country in which they are living, but that the question is not a fair suggestion of what has been done by the Bradford corporation?—Dr. Addison: I believe that is so.

THURSDAY, FEB. 26TH.

Health Measures at British Ports.

Lieutenant-Colonel Raw asked the Minister of Health whether his attention had been drawn to the arrival of a ship at a British port recently with cases of small-pox on board; and whether any steps were taken to deal specially with the danger of the introduction of infectious diseases through the ports of the country.—Dr. Addison replied: My attention has been drawn to the case to which presumably my honourable and gallant friend refers. Like all similar cases, it was made a matter of special inquiry by one of the medical officers of the Ministry. I am giving detailed consideration to the danger of the introduction of infectious diseases through the ports of this country in view of the widespread prevalence of small-pox, typhus, and other epidemic diseases on the continent and abroad. Special arrangements have been made with the Foreign Office and the Colonial Office whereby periodical and continuous information is received and appropriate action taken. A weekly bulletin is forwarded from the Ministry to the medical officers of health of the port sanitary authorities in this country, and special bulletins as occasion requires. I have been in communication with the port sanitary authorities on the whole subject, and I am convinced that the powers at present possessed by port sanitary authorities are inadequate. Regulations will shortly be issued with the object of obtaining a greater security against the introduction of infectious diseases into this country from abroad and of increasing the efficiency of port sanitary administration, and arrangements have been made with the Treasury for the provision of special financial assistance.

The Assessment of Disability.

Captain Loseby asked the Pensions Minister if he would make a statement clearly defining the practice of his department in regard to the assessment of pensions in cases in which it would appear that part of the disability was attributable and part was not attributable to military service.—Sir L. Worthington-Evans: If the honourable and gallant Member is referring to a man suffering from two disabilities, one of which is attributable to, or aggravated by, service and the other not so attributable or aggravated, pension is awarded in respect of that disability which is connected either wholly or in part with military service. In the case where a man who suffered from a disability prior to enlistment and on or after discharge is found to be suffering from the same disability in an aggravated form, the increase in disablement is considered attributable to military service and pension is assessed on the total extent of the disability.

Woman Representative for Welsh Board of Health.

Mr. Alfred T. Davies asked the Minister of Health whether the Welsh Board of Health included a woman representative, and if not, whether he intended to appoint such a representative, having regard to the fact that the Welsh Insurance Commissioners included a woman member.—Dr. Addison replied: The answer to the first part of the question is in the negative. An increase in the present composition of the Welsh Board of Health is just now under consideration, but I am not yet in a position to make a statement. The particular point referred to by the honourable Member will be borne in mind.

Influenza Inoculation in the Army.

Mr. LUNN asked the Secretary for War whether at any time during 1918 and 1919 consignments of assorted anti-influenza vaccines, each labelled distinctively, were sent to army medical officers in charge of troops, with instructions to inoculate batches of soldiers with the different vaccines and to note carefully the effect of each vaccine as regards preventing influenza; whether instructions were sent to medical officers that they should inform the soldiers that the inoculation was entirely voluntary; and whether some of the medical officers who made the trial found that the vaccines had no effect at all in preventing influenza.—Mr. CHURCHILL replied: The honourable Member is misinformed; no consignments of assorted anti-influenza vaccines have been issued to army medical officers. Anti-influenza vaccine of a composition decided upon by a conference of specialists, and prepared at the Royal Army Medical College, has been issued to commands. Prior to this a limited amount of vaccine prepared at Guy's Hospital was used in one command. These vaccines were only used in cases of men who volunteered to be inoculated. Medical officers were instructed to prepare statistical returns showing the incidence, deaths, and occurrence of pulmonary complications amongst inoculated and uninoculated persons. As regards the second part of the question, all inoculations with vaccines in the British Army are, and have always been, voluntary, and no special mention of the point was made when instructions were issued as to the use of this vaccine. As regards the last part, the general opinion of medical officers has been that the vaccine affords some protection against attack and distinctly lessens the incidence and severity of pulmonary complications.

MONDAY, MARCH 1ST.

Medical Officers in India.

Lieutenant-Colonel BUCKLEY asked the Secretary for War if he was aware that many officers of the Royal Army Medical Corps serving in India had been in that country for nine or ten years and appeared to have little prospect of relief; and if he would state what steps were being taken to expedite their relief.—Mr. CHURCHILL replied: There are 41 officers of the Royal Army Medical Corps still in India whose tour of service has expired, and every effort is being made to release them as other Regular officers become available. Twenty-four officers are under orders to proceed to India, and these will be employed for the relief of tour-expired officers and towards completing the permanent establishment of the Royal Army Medical Corps in India.

Lieutenant-Colonel BUCKLEY asked the Secretary for War if officers of the Royal Army Medical Corps serving in India were precluded from resigning their commissions; and, if so, what was the reason for this.—Mr. CHURCHILL replied: Instructions have been issued that Regular Royal Army Medical Corps officers serving in India cannot be permitted to resign their commissions until the statutory date of the termination of the war. This step was rendered necessary by the fact that India is much below peace establishment and that at present it is not possible to provide Regular Army Medical Corps officers to replace those who were desirous of relinquishing their commissions.

Small-pox in Germany.

Mr. LUNN asked the Minister of Health whether he had received any information as to the prevalence of small-pox in Germany during the years 1918 and 1919; and, if so, whether he could give the number of cases and deaths occurring and the districts in which they were notified, with any other information that was in his possession.—Dr. ADDISON replied: There had been an epidemic of small-pox in Germany during 1917, comprising some 3000 cases, the origin of which was traced to infection brought into Germany by Russian prisoners. During 1918 cases continued to occur, amounting, so far as our information goes, to about 300 in number. In December of that year there was a recrudescence of the disease, and up to the end of 1919 about 4344 cases had been reported; of this number some 800 occurred in Dresden and about 164 at Dantzig. Among the places in which small-pox was prevalent in 1919 were: Oppeln (311 cases), Konigsberg (88), Stettin (24), Breslau (58), Berlin (25), and Cassel (34), but the number of deaths has not yet been reported. In 1917 and 1918 there were many foreigners in Germany—prisoners, refugees, and others, including Russians, Poles, Austrians, Italians, Belgians, and French; and it is more than probable that many of these foreigners were unprotected by vaccination. The information that has reached us does not include separate statistics as to the number of Germans and foreigners respectively who were attacked during 1918 and 1919, or the number of deaths in each category.

National Health Insurance Bill.

Dr. ADDISON presented a Bill "to amend the Acts relating to National Health Insurance."

TUESDAY, MARCH 2ND.

Discontent among R.A.M.C. Officers.

Sir WATSON CHEYNE asked the Secretary for War if he was aware of the grave discontent among the Special Reserve and Territorial Force officers of the Royal Army Medical Corps in Mesopotamia owing to the fact that they could not get leave, some having spent two, or even three, hot seasons in Mesopotamia without leave; and, especially in view of the prospect of having to spend another hot season there, would he take steps to give relief to these men.—Mr. CHURCHILL replied: Many of these officers, in common with those of the Regular Royal Army Medical Corps and the Indian Medical Service, have leave due to them. This is a matter for the local military authorities, but I would remind my honourable and learned friend that the granting of leave must necessarily interfere with the release of officers eligible for demobilisation. Regular officers of the Royal Army Medical Corps are being sent out as they become available to replace officers of the Special Reserve and Territorial Force whose demobilisation has been applied for.

Medical News.

UNIVERSITY OF LONDON.—The Senate has appointed Dr. James McIntosh to the University chair of pathology at Middlesex Hospital Medical School, and Dr. Sidney Russ to be the first incumbent of the Joel chair of physics. The Senate has resolved to organise a course of lectures on mental deficiency for medical officers of local authorities and institutions and medical men engaged in work for defectives.

Chair of Radiology tenable at the Middlesex Hospital Medical School.—On the tragic death of Mr. C. R. C. Lyster the authorities of Middlesex Hospital and Medical School were faced with the immediate necessity of appointing an officer in charge of the X ray and electro-therapeutic department. It had been felt for some time that if real progress was to be made in radiology in this country, it was necessary to ensure that an expert in this branch of medicine should be able to devote his whole time to the charge of this department of the hospital and to the work of education and research. With this object in view, the hospital authorities approached the University of London to secure coöperation in achieving their object by giving high academic position to any whole-time officer appointed. At a meeting of the Senate on Feb. 25th a resolution was passed instituting a University Chair of Radiology tenable at the school. Opportunities for the investigation of the possibilities of radiotherapy at the Middlesex Hospital are very great. Over 100 beds are constantly occupied with cases of cancer; in the physics department there are special laboratories for the investigation of physical and pathological problems; also a large supply of radium has been obtained. Intimate connexion will be maintained between the new department and that of physics, and from this association progress is anticipated in the treatment and cure of cancer. The department will be of service to men proposing to specialise in radiology, a branch of medicine which has lately been recognised by Cambridge University as worthy of a diploma. The maintenance of the new professorship will be a financial strain for the institution to bear, but it is hoped that some assistance may be obtained by gifts for the purpose of endowment.

UNIVERSITY OF BELFAST.—In consequence of the great development of the department of anatomy, it has been decided to establish a class in human embryology, to abolish the class of elementary anatomy, and substitute a system of tutorial instruction, arranged in connexion with the practical class, and to establish a revision class. New regulations for the department of applied anatomy have also been sanctioned.

THE Middlesex Hospital has benefited to the extent of £5000 by the exhibition of nurseries at the Ideal Homes Exhibition.

PURSES FOR THE LONDON FEVER HOSPITAL.—At a reception held at the Mansion House on Feb. 26th Princess Mary received purses on behalf of the London Fever Hospital, including a donation of £1000 from Lady Strathcona. This hospital, which has 178 beds, is the only one in London other than the institutions supported by the rates to which infectious cases can be sent, and is in great danger of having to close its wards owing to want of funds. As Lord Balfour of Burleigh, the president of the hospital, pointed out, a subscription to the institution is a form of insurance against infectious disease, and a governor is entitled to free treatment for any member of his household. During the war 500 officers, nurses, and soldiers were treated in the London Fever Hospital.

Oxford Ophthalmological Congress.—The next meeting of the Oxford Ophthalmological Congress will be held on Thursday and Friday, July 15th and 16th, at Keble College, Oxford. A discussion on "Perimetric Methods" will be opened by Dr. Luther C. Peter, of Philadelphia, U.S.A. Members intending to take part in the discussion or able to contribute cases, specimens, new operations, or novelties of any kind are requested to send in their names to the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton. The Doyne Memorial lecture will be delivered on July 16th by Mr. F. Richardson Cross on "The Nerve Paths and Centres Concerned with Sight."

Residential Tuberculosis Treatment: Conference of Medical Officers.—A representative Conference of Medical Superintendents of Sanatoriums, Training Colonies, and Hospitals for Tuberculosis was held at 122, Harley-street, London, W., on Feb. 23rd. It was unanimously decided to form a new society, which should have as its aim the improvement of the methods of administration, diagnosis, and treatment of tuberculosis in residential institutions. Membership is limited to medical men and women whose duties lie mainly in the medical charge of residential institutions for the treatment of tuberculosis. "Associate members" may be elected from among those who have formerly held such posts, and from junior officers at present at such institutions. The annual subscription was fixed at 10*s*. 6*d*. for members and 5*s*. for associate members. It is intended to hold quarterly meetings, and to circulate among members full reports of the conclusions and recommendations of the society and its committees. Office bearers were elected as follows: Dr. Jane Walker (President), Dr. James Watt (secretary and treasurer); executive committee: Drs. Esther Carling, Elwin H. T. Nash, Marcus Paterson, A. Niven Robertson, P. C. Varrier-Jones, R. C. Wingfield, George Jones, and Sir Henry Gauvain. Small committees were appointed to collect information and to formulate recommendations, for report to the next meeting of the society to be held in May, on various questions relating to the standards of treatment and administration in institutions. Among these are the comparison of scales of dietary, the standards of medical and nursing staff, the methods of dealing with advanced and dying cases, the coördination of statistics, the relative values of different methods of treatment, and the construction and equipment of institutions.

Central Midwives Board.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Feb. 19th, with Sir Francis H. Champneys in the chair. Two midwives were struck off the roll, the following charges, amongst others, having been brought forward in the case of one of them:—

> That being in attendance at a confinement the midwife was guilty of negligence in the following respects. The patient, suffering from illness with abdominal pain, offensive discharge, and raised temperature, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 20; the patient being in the condition aforesaid, the midwife neglected to hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might immediately be forwarded to a medical practitioner or to an approved institution, as required by Rule E. 20; she neglected to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; neglected to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution at any time, as required by Rule E. 8, and she neglected to disinfect her hands and forearms before touching the generative organs of the patient, as required by Rule E. 14. Medical aid having been sought for the patient, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a), and the case being one supposed to be infectious, she neglected to send to the local supervising authority the notification required by Rule E. 6, and the notification that she was herself liable to be a source of infection pursuant to Rule E. 22 (1) (e). Being in contact with a case supposed to be infectious, the midwife attended another case in her confinement and continued to visit her without having undergone the disinfection prescribed by Rule E. 6. The midwife did not enter records of the pulse and temperature of her patients in a note-book or on a chart carefully preserved, as required by Rule E. 14, and did not keep her register of cases as required by Rule E. 24.

David Lewis Northern Hospital, Liverpool.—Many interesting questions were touched upon at the annual meeting of the David Lewis Northern Hospital, held in the Liverpool Town Hall under the presidency of the Lord Mayor, on Feb. 27th. In submitting the annual report Mr. W. H. S. Oulton, vice-chairman of the hospital, stated that its keynote was the word "increase." There had been increases in everything during the year. The number of in-patients had increased by several hundreds, the names of pensioners treated had doubled, and the number of out-patients had increased by 15,000. The staff had been increased, not only because of the greater number of patients, but also because they felt that the nurses should work fewer hours. Salaries had also been made larger, and the expenditure on foodstuffs, surgical and medical appliances, &c., had also gone up. The committee had done its best, but they could not run a first-class hospital on third-class rates. He made a special appeal to the working classes to support the hospital, which is situated near the docks in a working-class neighbourhood where accidents are common. The working man was a sportsman, and if made to realise that the hospital supplied him with the highest medical and surgical skill he would feel it his duty to contribute more generously to its maintenance. The financial statement showed that the expenditure for the year amounted to £32,161, and the income to £26,973, being a loss on the year of £5188, to which had to be added £6953, the debit balance carried forward from the previous year. In submitting these figures the honorary treasurer, Mr. W. B. Stoddart, stated that had it not been for the income derived from the maintenance of soldiers and pensioners, from the Public Health Department, and from private patients, the financial position of the hospital would be deplorable. In his capacity as treasurer it had been his duty to approach many rich men for subscriptions, and the universal attitude seemed to be that they had ceased to subscribe to the hospitals because they felt that such institutions should be supported by the rates. He had, however, information that made it quite clear to him that the Government had no intention of taking over the voluntary hospitals.

In moving the adoption of the report and accounts the Lord Mayor stated that he did not think the voluntary hospitals would ever be placed on the rates, but he thought that the time was ripe for such bodies as the corporations, vestries, and other local authorities to agree to give some sort of subsidy to the different hospitals. The matter was actually being considered at the present time, and he hoped for a sympathetic decision. Personally he thought it would be a mistake if the voluntary hospitals were taken over either by Government or by the municipalities. Such a step would impoverish us in the grace of charity, for the diminution of individual interest in the hospitals would be enormously to their disadvantage. He had great hope that the scheme, initiated by his predecessor in office, to raise £80,000 for the voluntary hospitals would do much to relieve the situation in which, at present, all the hospitals in the city found themselves. Already close on £46,000 had been raised, which was a proof that voluntary giving was not yet dead.

The Royal Hospital for Women, Shaw-street, Liverpool, has received a generous donation of £10,000 from Mr. and Mrs. John Rankin, who took this practical method of expressing their admiration of what they had seen during a visit paid to the institution recently.

The late Dr. F. W. S. Culhane.—Frederick William Slater Culhane, who died at Hastings on Feb. 15th, had only recently retired from the office of medical superintendent of Hastings Workhouse, which he had held for a long time. He was a past president of the East Sussex Medico-Chirurgical Society, and held the office of treasurer. A University College man, he took the L.S.A. diploma in 1877, and became M.R.C.S. Eng. in 1878.

King Edward VII. Hospital, Cardiff.—An appeal has been issued by the Lord Mayor of Cardiff for £150,000 on behalf of the King Edward VII. Hospital, Cardiff. It is not the intention of the board of management to erect further buildings on the present site, but the money is urgently needed to enable the hospital to complete its buildings and extend its accommodation and equipment to meet the growing demands made upon it. At the present moment there are 267 beds available and 1090 patients on the waiting list. A large scheme of extension was decided upon in 1915–16 with a view to provide a further 170 beds. It is essential to the efficient working of the hospital that adequate and suitable accommodation should be provided for the nursing staff, many of whom now have to be lodged in adjacent houses. When the new wards are completed a nursing staff of 250 will be utilised, and a nurses' home is urgently required. The appeal is addressed especially to the employers of labour and the workmen engaged in the South Wales and Monmouthshire area, since the King Edward VII. Hospital is the principal centre for the relief of sickness within this area; but those interested in the Welsh National School of Medicine, of which the hospital is an essential part, are also specially concerned. Subscriptions may be sent to the Lord Mayor of Cardiff, City Hall, Cardiff.

An out-patient department in psychiatry has been arranged at the hospital. When, in due course, a psychiatric clinic for in-patients is established in Cardiff it is proposed that the out-patient clinic be and remain part of the out-patient department of the hospital. As soon as the necessary arrangements have been carried out cases of mental and associated trouble in their early phases will be able to receive advice and treatment at the new out-patient department.

WOMEN will be granted admission to the Fellowship of the Royal College of Surgeons of Edinburgh.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—Hospitals in the County of London, or within nine miles of Charing Cross, desiring to participate in the grants made by this Fund for the year 1920 must make application before March 31st to the honorary secretaries, 7, Walbrook, E.C. 4. Applications will also be considered from convalescent homes which are situated within the above boundaries, or which, being situated outside, take a large proportion of patients from London. Applications will also be considered from sanatoriums for consumption which take patients from London, or which are prepared to place beds at the disposal of the Fund for the use of patients from London hospitals.

Distribution of Surplus Red Cross Funds.—The latest date for the receipt of applications for grants out of the special distribution of surplus Red Cross Funds, in aid of schemes of extension or improvement at London hospitals which can and will treat ex-soldiers or ex-sailors, is March 12th.

BRIGHTON DENTAL HOSPITAL.—The Governors of the Brighton, Hove, and Preston Dental Hospital at their annual meeting on Feb. 27th approved of a scheme to amalgamate with the hospital the Public Dental Service, a provident dental institution carried on in the same building, which receives payment by instalments from the patients. The facilities for free treatment in urgent cases are still to be available, and under the new regime the hospital will cover the whole range of dentistry, instead of confining itself to purely operative work.

THE LATE DR. T. G. ALDERTON.—Thomas Gunton Alderton, who was well known both as a general practitioner at Hammersmith and as honorary treasurer of the Medical Defence Union, died on Feb. 22nd in his seventieth year, following an attack of hemiplegia which occurred about four months ago. He was educated at Epsom College, and qualified with the M.R.C.S. Eng. and L.R.C.P. Lond. in 1874. He served as house physician to the Hospital for Diseases of the Chest, Victoria Park, and later as house surgeon at the West London Hospital, where he was afterwards appointed anæsthetist, becoming consultant anæsthetist on retirement from the active staff. He was the first honorary secretary of the West London Medico-Chirurgical Society, of which he was president in 1890–91, and at the time of his death treasurer. He was also the treasurer of the Cavendish Lodge of Freemasons, which was founded by some of the staff of the West London Hospital and which was one of the earliest medical lodges to be consecrated in London. Among the local appointments which he held were those of surgeon to the Convent of the Sisters of Nazareth and medical attendant to the St. James's Home, Fulham. Dr. Alderton was a man of sound judgment and sterling character, and his death is a loss to the professional world.

LEICESTER PUBLIC MEDICAL SERVICE.—The board of management, in presenting a report of the Leicester Public Medical Service for 1919, records an increase in the rates of contributions paid by subscribers to the service, which came into operation in July last. Special reduced rates are charged to subscribers who are in receipt of Old Age Pensions and to those who are receiving assistance from the guardians. The Leicester Public Medical Service provides free medical treatment for the uninsured blind of Leicester, and also for members of the Cripples Guild and the Wycliffe Society for Helping the Blind. The Education Committee has continued the arrangement with the board, whereby the school clinic work is carried on at the Central Dispensary, and 3135 new cases, in addition to many others, received treatment during the year, comprising vision, 580; nose, ear and throat, 602; and teeth, 1953. The board recently decided to set up and equip a pathological laboratory at the Central Dispensary. Various articles of equipment have been acquired from the Medical Research Committee, and Dr. T. C. Clare has been appointed pathologist.

The committee of the Leicester Subdivision of the Union of Medical Practitioners, in presenting their report for the year 1919, states that the scheme under which arrangements were made for giving medical attendance to patients of doctors absent on military service will henceforth be discontinued, since the need for it no longer exists. The success of a scheme for collective locum tenancies during the summer holidays is recorded. Thirteen practitioners availed themselves of the facilities and contributed £163 16*s*. to the pool. A scheme on similar lines for collective locum tenancies during sickness or short absences has just been arranged, to remain in force until March 31st. The following officers were elected for the ensuing year: Dr. E. Lewis Lilley (chairman), Dr. A. Foster (vice-chairman), Dr. Astley V. Clarke (treasurer), and Dr. W. Moffat Holmes (honorary secretary).

A MATINEE, to celebrate the jubilee of the Ladies' Association of the Great Northern Central Hospital, Holloway, N., will be held at the Palladium in May next.

THE LATE DR. F. M. NEWTON.—Francis Morley Newton, who died on Feb. 15th at the age of 45, was a student of St. Bartholomew's Hospital and qualified M.R.C.S. Eng., L.R.C.P. Lond., in 1905. After holding a resident post at the Bagthorpe Infirmary, Nottingham, he became resident medical officer to the Stoke-upon-Trent Workhouse Infirmary some ten years ago, and had held this post ever since. He was public vaccinator to the Stoke-upon-Trent rural district, and during the war acted as anæsthetist to the local war hospital.

TUBERCULOSIS IN DEVON.—At a recent meeting of the Torrington rural council the chairman stated that there were 1000 cases of "consumption" not notified in the county. The medical officer of health remarked that it was the duty of medical men who attended these cases to notify them, and unless they did so some action would have to be taken.

SOUTHMEAD HOSPITAL, BRISTOL.—At a recent meeting of the Bristol guardians it was stated that the Southmead Hospital, completed in 1914 and used till recently as a military hospital, would shortly be opened for the sick poor. It provides 544 beds, and is situated on the edge of the city at a height several hundred feet above sea-level. There is ample room for expansion. It is intended to appoint a team of consultants to act with the permanent staff of the hospital, and to make some provision for patients able to pay a small sum for their treatment.

BRISTOL ROYAL INFIRMARY.—The Duchess of Beaufort and other ladies have issued an appeal "to women for women," asking for £15,000 to maintain 30 beds for three years in the maternity department of the Bristol Royal Infirmary. These beds are available now that the soldiers have left the Royal Edward Memorial Wing of the institution, and it is confidently expected that the required sum will be subscribed.

ROYAL DEVON AND EXETER HOSPITAL.—The annual meeting of the subscribers to this institution was held on Feb. 26th. The financial statement showed that the ordinary expenditure exceeded the ordinary income by £2060. The chairman (Sir Chaning Wills) stated that when the new wing was completed the annual cost of working it would be about £10,000. A member alluded to a suggestion, made at the annual meeting of the Exeter Dispensary, as to the amalgamation of that institution with the hospital. It was stated that a subcommittee of the dispensary had been appointed to approach the hospital authorities on the matter. The meeting decided that the hospital committee should consider the subject before receiving the delegates.

PAYING PATIENTS AT THE PAIGNTON HOSPITAL.—At the annual meeting of the friends of the Paignton (Devon) Hospital it was decided that private patients who pay $2\frac{1}{2}$ guineas weekly shall in future pay their medical attendant. It was stated that some patients were trying to gain admission to the hospital who were in a better financial position than the medical men.

OCKENDEN CONVALESCENT HOME, TORQUAY.—At the annual meeting of the subscribers to this institution, recently held, the medical report stated that 258 patients had been admitted, with an average stay of 29 days. Dr. A. E. Carver, honorary physician, and Mr. H. K. Lacey, honorary surgeon, who had both held their appointments for 15 years, were awarded a hearty vote of thanks for their services.

DEATH OF DR. E. C. FENOULHET.—Edward Cooper Fenoulhet, a well-known Herne Bay practitioner, died at his residence recently in his sixty-seventh year. He received his medical education at Queen's College, Galway, and at St. Mary's Hospital, London, and obtained the L.M., Coombe Hospital, Dublin, in 1879, later taking the L.R.C.P. & S. Edin. Dr. Fenoulhet was an examiner, lecturer, and honorary member of the St. John Ambulance Association and senior honorary medical officer to the Herne Bay Cottage Hospital; he was also a justice of the peace for Kent.

THE LATE DR. J. PINKERTON.—James Pinkerton, who died on Feb. 16th, aged 58, was a student of Queen's College, Belfast, an exhibitioner of the Belfast Royal Hospital in 1880, and a Coulter exhibitioner in the following year, when he graduated M.D., M.Ch., and L.M. in the Royal University of Ireland. In 1883 Dr. Pinkerton went to Liverpool, where he was appointed resident medical officer of the Brownlow Hill Infirmary, and was afterwards elected to the staff of the Birkenhead and Wirral Children's Hospital. He took an active interest in the Children's Convalescent Home at West Kirby, to which he was a visiting physician.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

Thursday, March 11th.—Papers:—Mr. W. G. Duffield, Mr. T. H. Burnham, and Mr. A. A. Davis: The Pressure upon the Poles of Metallic Arcs, including Alloys and Composite Arcs (communicated by Prof. O. W. Richardson).—Mr. J. H. Vincent: Further Experiments on the Variation of Wave Length of the Oscillations generated by an Ionic Valve due to Changes in Filament Current (communicated by Prof. W. H. Bragg, O.B.E.)—Mr. H. A. Daynes: (1) The Theory of the Katharometer (communicated by Prof. S. W. J. Smith); (2) The Process of Diffusion through a Rubber Membrane (communicated by Prof. S. W. J. Smith).

ROYAL SOCIETY OF MEDICINE 1, Wimpole-street, W.

Thursday, March 11th.

OCCASIONAL LECTURE: at 5 P.M.

Sir Jagadis Bose, C.I.E., C.S.I.: Plant and Animal Response (with Demonstration of Growth by the Magnetic Crescograph).

MEETINGS OF SECTIONS.

Wednesday, March 10th.

SURGERY: SUB-SECTION OF PROCTOLOGY (Hon. Secretaries—W. Sampson Handley, Sir Gordon Watson): at 5.30 P.M.

Cases:

Mr. Lockhart-Mummery: Case of Double Growth in Colon.
Mr. Graeme Anderson: Syphilitic Stricture of Rectum.
Mr. Gabriel: Intestinal Obstruction following Abdomino-perineal Excision.

And other cases.

Thursday, March 11th.

NEUROLOGY (Hon. Secretaries—P. W. Saunders, George Riddoch): at 8.30 P.M.

Professor J. S. B. Stopford: Results of End-to-end Suture of Peripheral Nerves.

Friday, March 12th.

CLINICAL (Hon. Secretaries—T. P. Legg, S. A. K. Wilson): at 5 P.M.

Exhibition of Cases.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday, March 8th.—8.30 P.M., Dr. L. E. Hill: Heat Hyperpyrexia—the Clinical Aspect.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

Wednesday, March 10th.—4.30 P.M., Paper:—Mr. H. M. Thornton: Gas in Relation to Industrial Production and National Economy.

Wednesday, March 10th.—9 P.M., Papers:—Dr. F. H. Humphris: Modern Physiotherapy.—Mr. J. E. H. Roberts: The Treatment of Septic Fingers.

CHILD STUDY SOCIETY, LONDON, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

Thursday, March 11th.—6 P.M., Miss M. J. Reaney, D.Sc.: The Educational Needs of Adolescence.

HARVEIAN SOCIETY, at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.

Friday, March 12th.—8.30 P.M., Harveian Oration:—Sir Thomas Horder: The Diagnostic Significance of Nerve Symptoms in Acute Infections.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

Tuesday, March 9th, AND Thursday.—5 P.M., Goulstonian Lectures:—Dr. J. L. Birley, C.B.E.: The Principles of Medical Science as Applied to Military Aviation. (Lectures I. and II.)

UNIVERSITY OF LONDON.

Advanced Lectures in Physiology to Students of the University and others interested in the subject.

A Course of Eight Lectures on Physiologically Balanced Solutions will be given by Dr. W. L. Symes in the Physiological Laboratory of the University, South Kensington, S.W.:—

Tuesday, March 9th.—5 P.M., Lecture VII.

A Course of Eight Lectures on the Reaction of the Blood and Acidosis will be given by Dr. J. W. Trevan, at St. Bartholomew's Hospital, West Smithfield, E.C.:—

Wednesday, March 10th.—4.30 P.M., Lecture VII.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Mile End, E.

A Course of Instruction on the Diseases of Children, open to Post-Graduates and to Students of the Hospital. (The lectures will be illustrated by lantern slides.)

Wednesday, March 10th.—10 A.M., Clinical Demonstration:—Dr. Miller. (At the Children's Out-patient Department.)

Saturday.—10.15 A.M., Lecture X., Dr. Hutchison: General Diseases. (At the Anatomical Theatre.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).

A Course of Lectures on Syphilis is being given by various members of the staff of King's College Hospital during the present year.

Friday, March 12th.—9.15 P.M., Mr. A. Cheatle: Syphilis of the Ear.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, POST-GRADUATE COURSE, Westmoreland-street, W.

Monday, March 8th.—11 A.M., Out-patients: Dr. Goodall. 2 P.M. In-patients: Dr. Moon.

Tuesday.—2 P.M., Out-patients: Dr. R. Wells. 3 P.M., In-patients: Dr. Gibbes.

Wednesday.—2 P.M., Out-patients: Dr. Moon. 5.30 P.M., Lecture:—Dr. Gibbes: Pericarditis.

Thursday.—10 A.M., In-patients: Dr. Hamill: 2 P.M., Out-patients: Dr. Price.

Friday.—2 P.M., Out-patients: Dr. Gibbes. 2.30 P.M., In-patients: Dr. Wells.

Saturday.—10.30 A.M., In-patients: Dr. Hamill.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Special Course of Lectures and Demonstrations on Tuberculosis for Medical Men and Women qualifying to become Tuberculosis Officers, General Practitioners, and others. Bacteriological Demonstrations will be given in the Laboratories of the Institute, and visits arranged to Sanatoriums, Tuberculosis Dispensaries, &c.

Thursday, March 11th.—5 P.M., Lecture IX.:—Dr. H. M. Berry: X Ray in the Diagnosis of Tuberculosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, March 9th.—2 P.M., Demonstration (II.):—Dr. A. J. Whiting: The Early Diagnosis of Pulmonary Tuberculosis. 4.30 P.M., Lecture:—Dr. E. Jones: The Advantages and Disadvantages of Psycho-analysis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

Monday, March 8th.—2–3.30 P.M., Out-patient Clinic: Dr. Collier. 3.30 P.M., Ward Cases: Dr. Saunders.

Tuesday, March 9th.—2–3.30 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Dr. Risien Russell.

Wednesday, March 10th.—2 P.M., Mr. Sargent: Injuries of Peripheral Nerves and their Surgical Treatment. (II.) 3.30 P.M., Dr. Hinds Howell: Syphilis of the Nervous System. (II.)

Thursday, March 11th.—2–3.30 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Ward Cases: Dr. S. A. Kinnier Wilson.

Friday, March 12th.—2–3.30 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3:30 P.M., Dr. Gordon Holmes: Ataxia.

Saturday, March 13th.—9 A.M., Surgical Operations.

Fee for Post-Graduate Course £7 7*s*. C. M. HINDS HOWELL, Dean.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Saturday, March 6th.—10 A.M., Mr. Banks Davis: Operations of the Throat, Nose and Ear.

Monday, March 8th.—5 P.M., Mr. D. Armour: Operations for Hernia.

Tuesday.—2 P.M., Dr. Pernet: Demonstration of Skin Cases.

Wednesday.—2 P.M., Dr. Morton: Demonstration of Radiography.

Thursday.—2 P.M., Mr. B. Harman: Operation for Squint.

Friday.—5 P.M., Special Lecture:—Sir A. Pearce Gould: An Old Clinical Lecture, New Edition.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

Wednesday, March 10th.—4.30 P.M., Dr. Inman: Laboratory Methods in the Diagnosis of Tuberculosis.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Monday, March 8th.—3 P.M., Sir John Cadman, K.C.M.G.: (1) Modern Development of the Miner's Safety Lamp.

Tuesday.—3 P.M., Prof. A. Keith: British Ethnology: The Invaders of England. (Lecture II.)

Thursday.—3 P.M., Lieut.-Col. E. Gold, R.E., D.S.O.: The Upper Air.

CHADWICK PUBLIC LECTURES, in the Lecture Room, Royal Society of Arts, John-street, Adelphi, W.C.

Monday, March 8th.—5.15 P.M., Lecture:—General Sir John Goodwin, K.C.B., C.M.G., D.S.O.: Military Hygiene in Peace and War. I., Army Hygiene prior to the Recent War (illustrated by lantern slides).

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE DEMONSTRATIONS, at the Sheffield Royal Hospital.

Monday, March 8th.—3.30 P.M., Dr. Nutt: X Ray Examination of the Urinary System.

Tuesday.—4 P.M., Dr. Hay: Errors of Refraction.

Wednesday.—3.30 P.M., Dr. Wilkinson: Treatment of Suppurating Ears.

Thursday.—3.30 P.M., Dr. Skinner: Lupus, Lichen Planus, &c.

Friday.—4 P.M., Dr. Hay: Subjective Sight-testing

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, March 9th.—4.30 P.M., Dr. A. E. Barclay: X Ray Demonstration of Œsophagus and Stomach.

SALFORD ROYAL HOSPITAL AND ANCOATS HOSPITAL POST-GRADUATE DEMONSTRATIONS, at the two Hospitals alternately.

Thursday, March 11th.—4.30 P.M., Lecture:—Dr. Reid: Locomotor Ataxia. (At Ancoats Hospital.)

BRIGHTON DIVISION OF THE BRITISH MEDICAL ASSOCIATION, at the Sussex County Hospital.

Thursday, March 11th.—4 P.M., Clinical Demonstration.

WESTON-SUPER-MARE HOSPITAL.—At the annual meeting of the subscribers to this hospital, held last week, Dr. J. Wallace, on behalf of the Weston-super-Mare Red Cross Hospital, presented the hospital with £3070.

Appointments.

Hawker, G. P. D., M.D., B.C. Cantab., has been appointed Honorary Consulting Surgeon to the Exeter Dispensary.

Henderson, C. J., M.B. Durh., Assistant Medical Officer at the Royal Albert Institution, Lancaster.

Jones, W. H., M.B., B.S. Lond., Honorary Surgeon Anæsthetist to Charing Cross Hospital and Lecturer on Anæsthetics in the Medical School.

Mace, J. F., L.D.S. Eng., Honorary Dental Surgeon to the Ockenden Convalescent Home, Torquay.

Roper Saunders, W. E., L.R.C.P., M.R.C.S., D.P.H., Assistant County School Medical Officer for Durham.

Steele-Perkins, J. S. S., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Honorary Consulting Surgeon to the Exeter Dispensary.

Sullivan, W. C., M.D. R.U.I., Superintendent of Broadmoor Asylum.

Woodroffe, H. D., M.D., B.Ch., B.A.O. T.C.D., Medical Officer of Health for the Stratton (Cornwall) Rural District.

Certifying Surgeons under the Factory and Workshop Acts: Jefferiss, I. M., M.R.C.S., L.R.C.P., Lond. (Okehampton); Buchanan, T. A., L.R.C.P. & S.I., (Clogher); Logan, D. D., M.D. Glasg. (Newmains); Twamley, H. J., L.R.C.S. Irel., L.A.H. Dub. (Castle Hedingham); Brittain, P. M., L.S.A. Lond. (Hatfield).

Vacancies.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Dist. Res. M.O. £80.

Queen Mary's Hospital for East End, Stratford, E.—H.P. and H.S.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Two Asst. S.'s

Queensland, Institute Tropical Medicine, Townsville.—Physiologist and Biochemist. £700.

Reading County Borough.—M.O.H. £800.

Reading, Royal Berkshire Hospital.—Pathologist. £600.

Royal Free Hospital.—Temp. Asst. S.

Russian Red Cross Hospital in Near East.—M.O. £1000.

St. Bartholomew's Hospital and College.—Demonstr. of Pathology.

St. Mary's Hospital for Women and Children, Plaistow, London, E.—Res. M.O. £200. Also Surg. in charge X ray Dept. £50.

Salford Royal Hospital.—Res. S.O. £250. H.P. £200. H.S. and Cas. H.S., £150 each.

Salford Union Infirmary.—Sen. Res. Asst. M.O., Sec. Res. Asst. M.O. £350 and £300.

Scarborough Hospital and Dispensary.—Two H.S.'s £150.

Seamen's Hospital Society, Dreadnought Hospital, Greenwich.—P. 50 gs. Three Anæsth.'s. 50 gs. H.S. £100.

Sheffield Royal Hospital.—Asst. Cas. O. £150.

Sheffield Royal Infirmary.—Radiologist. £100.

Shrewsbury, Royal Salop Infirmary.—H.S. £250.

Singapore Municipality, Straits Settlement, Infectious Diseases Hospital, &c.—Med. Supt. £900. Asst. Health O. £750.

Stoke-on-Trent, North Staffordshire Infirmary.—Two H.S.'s. £200.

Sunderland County Borough.—Asst. M.O.H. and Maternity and Child Welfare M.O. £600.

Turks and Caicos Islands.—M.O. £400.

University of London.—External Examiners.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—P.'s.

Warwick County Lunatic Asylum.—Sec. Asst. M.O. £300.

West London Hospital, Hammersmith, W.—H.S., Asst. Anæsth.

Wigan County Borough Education Committee.—Part-time Dentist. £150.

Winchester, Royal Hampshire County Hospital.—H.S. £250.

Worcester County and City Lunatic Asylum, Powick, Worcestershire.—Med. Supt. £800.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Caldbeck, Hull, and Shaftesbury.

Births, Marriages, and Deaths.

BIRTHS.

Abel.—On Feb. 18th, at 21, Jenner House, Hunter-street, W.C. 1, the wife of A. Lawrence Abel, M.B., B.S. Lond., of a son.

Denning.—On Feb. 24th, at St. Catherine's, East Grinstead, the wife of Dr. Fredk. A. V. Denning, of a daughter.

Dodd.—On Feb. 25th, at 17, Ventuor Villas, Hove, to Dr. and Mrs. H. Grantham Dodd—a daughter.

Duggan.—On Feb. 20th, at College Gates, Worcester, the wife of Norman Duggan, M.B., F.R.C.S., of a son.

Graham Brown.—On Feb. 26th, at Sheerwater Lodge, West Byfleet, Surrey, the wife of L. Graham Brown, M.C., M.A., M.B. Oxon., of a daughter.

Roper Saunders.—On Feb. 5th, at 19, Devonshire-place, Jesmond, Newcastle-upon-Tyne, to Dr. and Mrs. Roper Saunders—a daughter.

Shattock.—On Feb. 27th, at 38, Mecklenburgh-square, W.C., to C. E. Shattock, M.S., F.R.C.S., and Mrs. Shattock (F. Mackenzie, M.B., B.S.)—a daughter.

MARRIAGES.

Dixon—Holmes.—On Feb. 28th, at St. Clement's Church, Bournemouth, William John Dixon, M.B., M.R.C.S., L.R.C.P., of Trong, Taiping, to Grace Gertrude, younger daughter of the late William Holmes, of Morton Hall, Gainsborough, and Mrs. Holmes, Bournemouth.

DEATHS.

Bonney.—On Feb. 29th, at Elm Park-gardens, S.W., of pneumonia, William Augustus Bonney, M.D., F.R.C.S., aged 79 years.

Burgess.—On Sunday, the 29th Feb., at the Red House, Lincoln, Dr. Andrew Burgess, of Canwick-road, Lincoln. Funeral at Canwick Church on Wednesday, 2.30.

Maturin.—On Feb. 24th, at Hartley Wintney, of apoplexy, Henry Maturin, M.R.C.S., L.R.C.P., aged 77.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS.

Malta.

THE report on the Blue-book for 1918-19 gives the civil population on April 1st last as 224,655. The birth-rate for the year was 30·09 per mille and the death-rate 26 30 per mille. The death-rate among children under 12 months was 244·60 per 1000 births, and that of children under 5 years was 107·06 per 1000 of the population of that age.

Influenza, marked by intercurrent or subsequent pneumonic infection, was the outstanding feature of communicable diseases in the islands. The number of deaths certified as due to influenza as a primary cause of one or other of the fatal complications was 685, equal to a mortality rate of 3·04 per 1000 of the population. Inclusion of all deaths from bronchopneumonia and pneumonia would bring this rate up to 4·11. As was expected, an increase in the number of deaths from pulmonary tuberculosis has been observed, and is accounted for by the injurious spurt set on by inter-current influenzal infection. Otherwise the state of health of the islands has been satisfactory. 4439 persons were successfully vaccinated. The mean temperature for the summer months of June, July, August, and September was 74·8, and for the winter months of January, February, and March 55·9. The total mean rainfall was 20·44, or 2·73 inches more than in 1917-18. The number of patients admitted into the hospitals of Malta and Gozo was 3974, and 145834 persons were attended by the district medical officers at the Government dispensaries or at their own residences. The number of inmates in the Leper Hospital on March 31st, 1919, was 93.

Trinidad and Tobago.

In his report for the year 1918, the acting Colonial Secretary, Mr. H. B. Walcott, says the estimated population of the two islands on Dec. 31st was 381,309. The white population is chiefly composed of English, French, Spanish, and Portuguese. The large majority of the inhabitants are natives of the West Indies of African descent, the balance being made up of East Indians, estimated at 129,300, and a small number of Chinese.

The birth-rate was 31·01 per 1000 and the death-rate 21·70 per 1000. The number of deaths of children under one year was 1628, and the infantile mortality was 138·4 per 1000 births. The death-rates from the principal diseases were: diarrhœa and enteritis, 2·02 per 1000: malaria, 2·20; tuberculosis, 1·44; dysentery, 0·78; enteric fever, 0·65; ankylostomiasis, 0·56. Measures for reducing the high infantile mortality in the colony were adopted during the year. The Government established a mothers' and infants' clinic at the Colonial Hospital, Port of Spain, where infants and expectant mothers were seen by a Government Medical Officer three times a week. The Notification of Births Ordinance now in force in Port of Spain provides for the notification of all births within 36 hours. A baby welfare league was started in 1918. There was no serious epidemic during the year. Influenza of a mild type was widespread, but was not attended by the high mortality observed in other countries. Hookworm disease, which seriously affects the labouring population, was treated on the intensive plan by the Rockefeller International Health Commission in a few districts, and the Central Board of Health instituted a campaign in all country districts with the object of effecting the provision of sanitary conveniences in connexion with all dwellings. The question of the housing of lepers was inquired into by a committee, whose recommendations were of great value, and a committee of medical men, under the chairmanship of the acting Surgeon-General, had under consideration the prevalence of venereal diseases and their control. Hospital accommodation in the islands includes 340 beds at the Colonial Hospital, Port of Spain, 123 at the San Fernando Hospital, and 246 at the Government District Hospitals in Tobago, Arima, St. Joseph, Tacarigua, Couva, Prince's Town, and Cedros. There are also small temporary hospitals at Chaquanas, Sangre Grande, Mayaro, and Toco. Hospitals for yaws patients are provided at St. Augustine (200 beds) and Tobago (160 beds).

Nigeria.

A delayed report on the Blue-book for 1917, prepared by Sir F. D. Lugard, G.C.M.G., C.B., D.S.O., Governor-General, states that in the Northern Provinces it was estimated that there were resident about 779 Europeans, of whom about 343 were officials. In the colony and Southern Provinces there were about 2000 Europeans, about 1250 being officials.

The native population of the Northern Provinces is estimated at 8,080,793, and of the Southern Provinces and colony at 7,856,000—a total of about 16 millions. The average density in the Northern Provinces would, therefore, be about 32 to the square mile, and in the Southern Provinces and colony about 98. Registration is compulsory in Lagos and Ebute Melta only, and the statistics from these places for 1917 showed: total births, 2846; total deaths, 2167; total deaths of infants under 1 year, 795; stillbirths, 141; infantile mortality per 1000 births, 279·3, In the Northern Provinces the cases treated of the five diseases, dysentery, malaria, blackwater fever, yellow fever, and trypanosomiasis, showed an increase, and malaria was responsible for, roughly, one-fourth of the total cases treated. In the Southern Provinces the general health compared rather unfavourably with that of the previous year. 132,878 cases were treated, of which 903 died, or a case mortality of 6·8 per 1000, as compared with 122,217 cases and 737 deaths in 1916, or a case mortality of 6·03 per 1000. There were 10,631 more cases reported than in 1916. This fact, however, can hardly be taken as an indication of an increase in the sick rate among natives, but rather as an indication, which has been noted annually in the past, of a greater inclination on the part of the native to avail himself of European methods of treatment.

With the exception of anæmia, general diseases are not frequently seen; there were 2 cases of diabetes, 7 of gout, 12 of exophthalmic goitre, 2 of leucocythæmia, and 3 of lymphadenoma. Eleven deaths were due to anæmia and 1 to leucocythæmia. Malaria, as usual, headed the list with 11,804 cases. There was 22 cases of blackwater fever in Europeans, with 11 deaths, and 5 cases occurred in natives, with 2 deaths. There were 6 cases (none fatal) of trypanosomiasis, 2 of which were in Europeans. Four cases of yellow fever occurred, of which 2 were in Europeans; 1 native and 1 European died of the disease. There were 2695 cases of chicken-pox reported and 231 of small-pox; also 12 cases of enteric, of which 3 natives died. Forty European officials and 34 European non-officials were invalided during the year, and there were 15 deaths among European officials and 8 among non-officials. Twenty-seven lepers were treated at the asylums at Yaba and Calabar.

Swaziland.

Mr. B. Nicholson, Government Secretary, in his report for 1918–19, states that the estimated population is now about 100,000, including 1700 Europeans. Amongst the latter there were during the year 9 marriages, 34 births, and 22 deaths. The births and deaths of natives are not registered.

Malarial fever was severe during the hot months and was accompanied in comparatively few cases by dysentery. There were a few cases of enteric. Cases of leprosy amongst the natives are discovered from time to time. The Swazis do not consider this disease to be infectious and steps are being taken more effectually to isolate known cases. The great epidemic of influenza which ravaged South Africa in the latter months of 1918 affected every part of Swaziland, but fortunately it appeared in a mild form. Extra doctors, nurses and orderlies were obtained through the Health Department of the Union Government, and everything possible was done through them, and, by the issue of free medicines, to alleviate the condition of those attacked. The natives, who had not hitherto taken a large advantage of the medical services of the territory, submitted freely to inoculation and to the administration of the medicines prescribed. During the epidemic the death-rate amongst the Europeans was ½ per cent., and amongst the natives approximately 1 per cent. The hospital at Mbabane is the only Government institution in the territory; it contains one European and two native wards. There were 133 admissions during the year and nearly 2500 out-patients were treated.

Basutoland.

Mr. J. P. Murray, Government Secretary, has issued his report for 1918 19.

He states that typhus fever, which had been prevalent in the Quthing and Qacnas Nek districts from August to December, 1917, had been entirely stamped out by May 11th, 1918. During the period there were 241 people affected, with 111 deaths. No further cases occurred during the year. The so-called Spanish influenza epidemic was rife in the months of October and November. In the absence of any registration of births and deaths no accurate statistics in regard to mortality from the disease are available. Apart from the direct observation of the medical staff, information obtained by the district officials from the native chiefs and from local statistics supplied by missionaries and traders, goes to show that the deaths in the territory may be safely estimated at 15,000. Probably 75 per cent. of the total population was affected. There has again been a notable decrease in the incidence of enteric fever. Dispensary and hospital work has been maintained at a high standard in spite of absence of some of the staff on war leave. The number of in-patients treated was 1984; out-patients (new cases) 23,078. On March 31st, 1919, there were 168 male and 181 female inmates in the Leper Asylum. During the year there had been 72 deaths, 9 births, 64 deserters, and 44 returned deserters. The high death-rate was due to the influenza epidemic, which also caused the greater number of desertions.

Bechuanaland Protectorate.

The health conditions for the year ended March 31st, 1919, as regards the incidence of general diseases, and relatively to predisposing and prevailing climatic influences, were above the average for the past few years.

Malarial disease, so far as it could be identified separately, was neither so prevalent nor so severe for the first half of the year. After that, however, the existence of the disease in the usual form was obscured by the epidemic of Spanish influenza, with which it revived and developed concurrently over the greater portion of the country. The mortality all round from influenza and its complications was estimated at between 4 and 5 per cent. of the population. Amaas, or modified small-pox, which was widespread amongst the various tribes two years ago, has, in consequence of the protection afforded by vaccination during that interval, all but disappeared; only one case was observed within the territory during the year.

PRACTICE IN JERUSALEM.

To the Editor of THE LANCET.

SIR,—With reference to your reply to "H. P. U. (U.S.A.)" in THE LANCET of to-day's date, as late D.A.D.M.S. in the Occupied Enemy Territory Administration of Palestine, I can inform you that a licence to practise is now granted to medical men and women who can produce diplomas of recognised universities and medical schools. This regulation was established about a year ago. A small fee is charged.

I am, Sir, yours faithfully,

Plymouth, Feb. 28th, 1920. F. J. SCRIMGEOUR.

THE AIR IN PUBLIC VEHICLES.

IT is stated that the London General Omnibus Company has arranged to spray motor omnibuses daily with disinfectant, and that the London County Council is considering the question of disinfecting tramway cars. It woul certainly be a satisfaction to the first traveller in an omnibu or tramcar to know that it was free from disease germs and th knowledge might afford him compensation for early rising But by 7 A.M. all public vehicles are full of micro-organisms some harmless and others pregnant with mischief for th susceptible traveller. Free ventilation and prevention o overcrowding are the only reliable safeguards, and so long a overcrowding seems to be unavoidable, ventilation needs t be in proportion. In so far as an antiseptic spray soothes th hygienic conscience to neglect the greater essentials, it ma do positive harm.

THE G. P. POCKET THROAT AND EAR OUTFIT.

Dr. Henry Dutch has adapted the common electric torc to the purposes of laryngology and otology by a device which consists of a metal collar fixed close to the lens of small cylindrical torch. To the periphery of this collar i attached a small piece of tubing through which runs a right angles to the plane of the collar a rod carrying at th forward end a laryngeal mirror, an ear speculum or a tongu depressor, as the case requires, the rod being adjusted by thumb-screw. Good illumination of the throat, fauces vocal cords, and the drum of the ear can be obtained, whil the laryngeal mirror can also be used with advantage fo examining the teeth. The device can be obtained from a surgical instrument-makers.

THE VOCAL THERAPY SOCIETY.

UNDER the auspices of this society a King's Service Choir, consisting of some 150 discharged and more less disabled soldiers, demonstrated at the South-Wester Polytechnic on Feb. 28th the benefit resulting from dee breathing and singing. The programme included "Th Trumpeter," "Up from Somerset," "Whisper and I Sha Hear," "Gallants of England," and the "Orderly," an the zest with which they were rendered bore amp testimony to the enjoyment of the singers. The practic sympathy and lack of conventionality on the part of Lad Carnarvon, the vice-president, and of the other officials of th society, obviously helps in no small measure to promote th success of the enterprise. We have already referred to th Vocal Therapy Society (THE LANCET, Feb. 7th, p. 358), th aims of which include the promotion through speech, son and efficient breathing of the mental health of the soldie in the hospitals and convalescent camps, and in discharg centres. In furtherance of these aims King's Services Choi are being formed in various places and the movement deserving of the heartiest public support. More tha 166.000 men have been discharged from hospitals medical unfit since the Armistice was signed, and both men a public will benefit if some of these can be made usef members of society by these means. Subscriptions shou be sent to the honorary treasurer, Mr. H. E. Bur 47, Lincoln's Inn Fields, London, W.C. 2.

THE INTERPRETATION OF MEDICAL CERTIFICATES.

Sir John Hope recently asked the Pensions Minister state in the House of Commons why the Midlothian Loc Pensions Committee, on June 18th, 1919, were ordered stop paying £1 9*s*. 7*d*. per week to Mrs. Maclaren, Dalkeit and in future only to pay 5*s*. 6*d*. per week; whether he w aware that Mrs. Maclaren had three young children support, and was the widow of Private T. Maclare No. 303407, 1/8th Argyll and Sutherland Highlanders, who death on Jan. 4th, 1919, was certified by the local medi officer to be the result of a wound received in action. reply, Sir L. Worthington-Evans stated that Priva Maclaren was discharged in August, 1917, for gunsh wound in the right leg and received a pension of 11*s*. week He died in January, 1919, from gastric ulcers, pericardit and heart failure, disabilities which, in the opinion of medical advisers, were not connected with his wound or wi his military service. In these circumstances the advanc provisionally made by the local committee could not be co tinued, and the widow was awarded a pension of 5*s*. 6*d*. p week under Article 17 of the Royal Warrant. In view, ho ever, of further evidence which has been submitted, t case is now being reinvestigated, and the decision will be delayed. If the decision is unfavourable to the wido she will be able to appeal to the Appeal Tribunal.

Sir John Hope rejoined that he had in his possessio medical certificate in which heart failure was not mention when Sir L. Worthington-Evans pointed out that the wido if a final pension is refused, has the right to appeal to independent tribunal; laymen must have extreme difficu in dealing with medical certificates.

Hunterian Lecture

ON THE

SURGICAL ASPECT OF DYSENTERY.

Delivered before the Royal College of Surgeons of England on Feb. 6th, 1920,

BY ZACHARY COPE, B.A., M.D., M.S. Lond., F.R.C.S. Eng.,

SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL; SURGEON TO THE BOLINGBROKE HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—Surgical complications are not common in dysentery; yet when the disease is very prevalent many occasions arise calling for the opinion of the surgeon, and not infrequently needing his operative interference. Every big military campaign produces its epidemic of dysentery, and the late war was no exception, for at Gallipoli, in Egypt, Mesopotamia, Persia, East Africa, and other places such numerous cases occurred that it should be possible to gain some knowledge from their consideration. Such knowledge would be all the more acceptable in that greater numbers of men are constantly going to and from the East, and that large numbers of latent, subacute, and chronic dysenteric patients are at present in this country.

The literature on the surgical aspects of dysentery is scanty, scattered, and not readily available; this fact, together with the difficulties and mistakes in the experience of the lecturer during service in Mesopotamia, serves as sufficient excuse for the present lecture. But, though during my stay in that country I saw the surgical complications incidental to one or two thousand cases of dysentery, in this short survey I have taken a wider outlook by giving information obtained from others whose combined experience enables me to speak more authoritatively than would be possible from my own work only.

The term dysentery is applied to the results of invasion of the large bowel either by the *Entamœba histolytica* or by various bacilli (Shiga, Flexner, Y-bacillus), which differ chiefly in their sugar-fermenting properties. At the same time, it is an open question whether one should not include under the same heading those cases of ulcerative colitis from which no specific organism has been obtained.

The amœbic infection leads to infiltration and ulceration of the intestinal wall. The ulcers are usually undermined and often scattered, and sometimes large areas are denuded of mucous membrane, whilst in severe cases of acute, sloughing, amœbic dysentery the bowel wall may be so rotten as to merit Rogers's apt simile of damp blotting-paper. In bacillary infection ulceration is not so constant a feature, but severe cases are accompanied by extensive sloughing of the mucosa, so that at autopsy there may be no particle of mucous membrane left in the large gut. Fever and toxæmia are more common features of the bacillary form of infection.

CONNEXION BETWEEN SURGERY AND DYSENTERY.

The surgeon may meet with dysentery in three ways: (1) Dysentery may develop as a complication of surgical conditions; (2) various surgical conditions may be simulated by dysentery; (3) complications needing the surgeon may arise in the course of dysentery.

1. *Dysentery as a complication of surgical conditions.*—When a patient has been the recent subject of dysentery it is no uncommon occurrence for the symptoms to be reawakened by the disturbance incidental to a surgical operation. Several times I have been alarmed by the development of acute dysentery in patients who before operation seemed perfectly healthy save for the condition needing interference. Probably the preliminary purgation is the main factor in awaking the disease, for it is well known that a purge will often bring back symptoms in a latent case of dysentery. Since some cases of malaria have dysenteric symptoms, examination of the blood and of the stools are needed for purposes of differentiation.

In long drawn out surgical diseases, for example, chronic suppurative conditions, where the body resistance is lowered, the onset of dysentery may determine a lethal result.

2. *Simulation by dysentery of surgical conditions.*—It is seldom that dysentery simulates surgical diseases. On one occasion a man over middle age was sent into my wards with a diagnosis of cancer of the rectum. The passing of blood and mucus with pain and tenesmus would certainly have led to that tentative diagnosis in this country, especially when, as in this case, an examination of the fæces showed no amœbæ. But after the preparation preliminary to a sigmoidoscopic examination, a further test of the fæces showed great numbers of amœbæ, and all the symptoms subsided under administration of emetine. Dysentery is frequently accompanied by piles, which must not be allowed to mislead the observer.

Sir Leonard Rogers has informed me of one case which was diagnosed by two surgeons as cancer of the rectum, and of another diagnosed as cancer of the cæcum, which were found to have amœbæ in the stools, and were cured by emetine. The same writer has known dysenteric cases diagnosed as tuberculous peritonitis, gangrene of the rectum, and intestinal obstruction.

The simulation of appendicitis by amœbic typhlitis and of cholecystitis by amœbic hepatitis will be touched on later, but the above errors in diagnosis are sufficient to warn the surgeon who works in a tropical country that he must ever be on the watch for dysentery.

3. *The surgical complications of dysentery.*—The surgical complications of dysentery may be classified into: A. Those due to local processes in the intestine. B. Those following on the remote effects of the organism or its toxins. C. Associated surgical conditions.

SURGICAL COMPLICATIONS DUE TO LOCAL PROCESSES IN THE INTESTINE.

Group A may be classified as follows: (i.) Perforation of colon causing general peritonitis, pericolitis, or pericolic abscess. (ii.) Acute œdematous localised colitis—for example, typhlitis. (iii.) Dysenteric appendicitis. (iv.) Extensive sloughing, the colon pus-sac. (v.) Cicatrisation and stricture of the colon or rectum. (vi.) Perinephric abscess. (vii.) Periproctitis.

(i.) *Perforation of Colon Causing General Peritonitis, Pericolitis, or Pericolic Abscess.*

In view of the extensive ulceration often occurring in the colon it is a matter of surprise that perforation is so uncommon. It is less common in bacillary cases. In 350 cases observed by Waller only one perforated, whilst Strong had three perforations in 200 amœbic cases. In Bartlett's statistics, out of 37 cases dying from amœbiasis or the direct result of dysenteric ulceration only three were due to perforation. Since it has been proved that perforations are sometimes cured naturally, it is possible that a perforating ulcer is more common than statistics show.

The most common sites of perforation are the cæcum and the sigmoid colon. The symptoms produced depend upon the position and direction of perforation of the ulcer.

(*a*) It may perforate into the general peritoneal cavity. In this case onset or increase of abdominal pain, vomiting, and collapse, rising pulse-rate, distension, and abdominal-wall rigidity may indicate the catastrophe, but in patients subject to a severe toxæmia the exacerbation of symptoms may not easily be distinguished from the collapse of toxæmia. If the perforation is diagnosed, what line should the surgeon take? The patient is often very weak, the bowel wall friable and unsuitable for suture, a surgical operation is very likely to have an immediately fatal issue, and, on the other hand, natural recovery has been known to occur. Rogers has pointed out that in bacillary cases the intestinal wall is not usually so friable, and would probably be more easily sutured. I think in most cases the question of operation would depend on the acuteness of the symptoms and the patient's reserve of strength. I have only been able to learn of two cases of successful suture of a dysenteric ulcer which had burst into the general peritoneal cavity. Both were under the care of Mr. C. C. Choyce, who is to be congratulated on these successes. The following case came under my observation.

J. R. M. began to have dysenteric symptoms on June 14th, 1918. The condition was recalcitrant to treatment, and on July 19th there was an acute attack of abdominal pain with rigidity of abdominal muscles and diminution of liver dullness. Perforation was diagnosed, but operation thought to be contra-indicated. The acute signs passed off, but intestinal hæmorrhage occurred and death from exhaustion took place on August 14th, nearly a month after perforation. At the autopsy there were 1½ pints of serous fluid and some flakes of lymph in the peritoneal cavity, and a localised abscess in the region of the mesosigmoid. There was gangrenous inflammation of the descending colon, iliac and pelvic colon, and rectum, with several thin areas sealed by omentum. There is no doubt that if the dysenteric process could have been controlled the patient would have recovered in spite of the perforation.

If operation should be considered advisable, spinal anæsthesia might be suggested, but for obvious reasons patients suffering from dysentery are not the best subjects for spinal injections. The technical difficulties in sewing up a rent in a very friable bowel wall must be considerable. In cases of perforation where the general condition is very poor as a result of toxæmia and exhaustion it is probable that by the adoption of the Fowler position, the injection of saline subcutaneously or intravenously, and possibly the administration of small doses of opium or morphine, the patient would stand as good (or as bad) a chance of recovery as if operation were performed.

(*b*) If perforation occurs retroperitoneally or after adhesions have formed round the thinned area of bowel wall an abscess may form and be amenable to surgical treatment. The most common region for such collections is the cæcal area, where the diagnosis may sometimes be difficult from appendicular abscess or non-suppurative dysenteric typhlitis. One case at Bagdad illustrated this point. There was a painful swelling in the right iliac fossa and amœbæ were found in the stools. I diagnosed amœbic typhlitis, but a colleague favoured the diagnosis of abscess; under treatment by emetine the swelling improved slightly, but a peritvphlitic abscess needed to be opened later. The correct diagnosis, I think, should have been localised perforation of the dysenteric cæcum. After the opening and drainage of abscesses resulting from localised perforation of the cæcum Novis states that not uncommonly the edges of the wound may become gangrenous. He adds that such a complication in some cases reacted well to injection of emetine and local application of carbolic acid.

(ii.) *Acute Œdematous Localised Colitis—Typhlitis.*

Dysenteric ulceration and inflammation may be limited to a circumscribed portion of the bowel. This is particularly the case with amœbic infection. Bartlett, in 26 autopsy cases in which amœbæ were found in the tissues, demonstrated that in 2 the descending colon alone showed lesions, in 3 the cæcum and ascending colon were alone involved, whilst in 6 others there was a limited affection of the large bowel. In 9 cases the cæcum showed the most advanced lesion. Now Rogers has laid stress upon the important fact that cæcal dysentery is often latent and does not so often give rise to the more urgent symptoms which result when the lower portions of the colon are involved. This fact was not known to me when first I went East. Hence it happened that from time to time I was faced with the clinical picture of swelling in the right iliac fossa accompanied by local pain and tenderness, which led to an operation under the supposition that there was an acute appendicitis. Operation in such cases revealed a greatly enlarged, œdematous, congested, and acutely inflamed cæcum with an appendix no more inflamed than would naturally result from the neighbouring inflamed cæcum. Such a definite typhlitis was on several occasions unaccompanied by any symptoms of dysentery when the patient came under observation. The only reference in the literature to this condition, apart from the references in Rogers's excellent book, is by Barry and Crump, who mention the simulation of appendicitis by large chronic dysenteric ulcers of the cæcum, and the production of severe intestinal hæmorrhage subsequent to some abdominal operation. But from correspondence and conversation with those who have had experience of dysentery cases in large numbers I gather that many have fallen into this error, though few have written about their mistake. Mr. Choyce, who has had a great experience of dysentery, tells me that in several hospitals he saw dysenteric typhlitis operated on for appendicitis, and on several occasions he was instrumental in stopping the operation when the surgeon had decided to operate. My own experience was rather bitter. Early in 1917 I operated on two patients at Nasiriyah in whom I had diagnosed appendicitis, but in whom I found a true typhlitis. Neither had dysenteric symptoms at the time of operation, but I suspected at the time that the typhlitis was of dysenteric origin. No harm resulted from these operations. At a later date the danger of interfering with such cases was brought home to me. A patient who presented symptoms of appendicitis proved at operation to have a much-thickened, juicy, congested cæcum and a congested appendix, which I removed. After the operation symptoms of acute dysentery developed, blood and mucus were passed frequently and in large quantities, and coma developed, ending in death within three days of the operation. About a year later I had a somewhat similar case with a happier ending.

Pte. E. was admitted to the 31 B.S.H. in July, 1918, as a walking patient, with constipation put down as the diagnosis on the field medical card. He had had attacks of diarrhœa alternating with constipation, as we subsequently found out. He was given an aperient the day after admission. On the third day after admission he complained of abdominal pain and had a temperature of 101° F. When I saw him a tender swelling could be made out in the right iliac fossa. A diagnosis of appendicitis was made and appendicectomy performed the same day. The appendix was swollen and inflamed, but the cæcum was still more congested and œdematous. Three days later very severe intestinal hæmorrhage occurred, and for several hours the radial pulse could not be felt. After 6 pints of saline had been given intravenously he rallied, but for days he continued to pass blood and mucus, and was troubled with incontinence of urine and vomiting. Then he became delirious, and passed more frequent and offensive stools. Emetine was then started (though neither amœbæ nor specific dysenteric bacilli had been found in the stools), and improvement was then uninterrupted.

These cases taught me my lesson, and I saw later several cases of dysenteric typhlitis which I diagnosed and cured by emetine. The importance of differentiating amœbic (dysenteric) typhlitis from appendicitis is clear, for while operation in the latter case is urgent, in the former it is fraught with peril. When such localised œdematous colitis affects the sigmoid, dysenteric symptoms are more likely to be present and local swelling and pain are less likely to give trouble in diagnosis. I have never seen a local dysenteric affection of the transverse colon, but Colonel T. P. Legge informed me that he saw a swelling of that portion of the gut disappear completely under treatment by emetine. I can do no better than repeat the words of Barry and Crump: "The surgeon will do well to weigh carefully the history of an attack of chronic dysentery before deciding upon an abdominal operation." To that I would add the recommendation that in countries where amœbic dysentery is endemic, the surgeon should have the fæces examined, and try a short course of emetine before operating on cases with symptoms of appendicitis accompanied by a swelling in the right iliac fossa.

(iii.) *Dysenteric Appendicitis.*

The vermiform appendix is affected by dysentery in common with the cæcum, but it is seldom that it gives rise to definite and separate symptoms. Usually this does not matter since both conditions improve together. If, however, perforation of the appendix should occur it would be considered necessary to operate. I had one such case.

A. M., 24 years, was admitted to 31 B.S.H. for corneal ulcer on August 2nd, 1918. On Sept. 14th, 1918, he developed abdominal pain and fever. On Sept. 17th he vomited and I was asked to see him. He presented a tender spot to the right of the middle line on the hypogastrium, tenderness per rectum on the right side of the pelvis, and rotation of the thigh caused hypogastric pain. (In passing I would like to call attention to the last-mentioned sign which I have never seen described, but which is sometimes a very useful help in diagnosing inflammation on the right side of the pelvis. It depends upon the movement of the obturator internus muscle, which causes pain referred to the hypogastrium when there is an inflamed mass adherent to the fascia covering it. This sign is no substitute for rectal examination, but when the latter is difficult or doubtful in a sensitive or stout subject useful aid may be obtained by its trial.)

I operated on this patient and found a large swollen appendix on the right side of the pelvis adherent to an adjacent coil of gut. There was no pus, but a very small perforation of the appendix with no escape of contents. The cæcum was very œdematous. I removed the appendix, but after operation the condition became worse. Hæmorrhage occurred from the bowel and right basal pneumonia supervened. The subcutaneous tissue of the wound became necrotic. There were no signs of peritonitis, but the patient had constant diarrhœa and incontinence of fæces. Death occurred nine days after operation. Autopsy showed extensive ulceration of the whole of the large bowel, whose mucous membrane had a leopard-skin appearance. *B. Shiga* was isolated after death.

I think in spite of the fatal complication the same symptoms would always demand operative treatment, though possibly earlier antidysenteric treatment might have been carried out. But the latency of the dysentery was deceptive, and since examination of the stools showed no specific bacillus or amœbæ a vaccine of *B. coli* had been given on the assumption that the condition was a *B. coli* toxæmia.

(iv.) *Extensive Sloughing: the Colon Pus-sac.*

The dysenteric process is sometimes so acute that large portions of the mucous membrane become necrotic. Sometimes the whole of the mucosa is destroyed, and then a fatal result is the rule. In less virulent cases extensive ulcerative surfaces are left, secondary infection supervenes, and the colon becomes virtually a pus-sac. It is then difficult or impossible to isolate the specific dysenteric bacilli, which, indeed, seem in most cases to be overshadowed by other bacilli within a few days of onset of the disease, as shown in the table of Martin and Williams:—

Period of disease.	No. of examinations.	Positive.	Percentage.
1–5 day	153	104	68·0
6–10 ,,	161	28	17·4
11–15 ,,	194	13	6·3
16–20 ,,	162	5	3·1
21–30 ,,	205	3	1·5
31–40 ,,	104	3	3·0
41–50 ,,	34	1	3·0

Carey Evans has pointed out that the majority of chronic dysentery cases are by no means simple infections. He remarks that at post-mortem examination the large intestine in such cases is an abscess cavity. So we must conclude that the patient is often well of his specific dysentery but ill from the ulceration and secondary infection which result from it. In such cases the physician, in addition to specific treatment, helps the evacuation of the toxic intestinal contents by the administration of aperients and by washing out the lower bowel from below. Can the surgeon be of assistance either (1) in the subacute stage, when the ulceration is taking place, or (2) when the colonic pus-sac is formed? In any case, it is assumed that the surgeon would not be needed until the art of the physician has failed to arrest the disease. This would exclude most cases of amœbic infection since they react to emetine so well.

(1) The general opinion is that surgical measures have no place in the acute or subacute stage. Cotte, however, has recently recorded seven cases in which he performed appendicostomy between the fifteenth and twentieth day of the disease when medical treatment had been of little or no avail. Five of the seven made a good recovery. Cotte washed out the colon with silver nitrate solution, 1 in 1000. In none of his cases did the operation appear to do harm, though it failed to save two patients. In the five successful cases recovery was prompt and permanent. It is hardly wise to draw conclusions from such few cases, though clearly the procedure is not so unreasonable as some have assumed.

(2) In chronic dysentery, especially the bacillary variety, when the sloughs which have come away make it clear that large ulcerating surfaces are present, and the clinical condition of the patient gives evidence that he is being slowly poisoned by the toxins which are being absorbed, the problem is less doubtful. Irregular fever, rapid pulse-rate, anæmia, emaciation give the clinical picture which ends in death from asthenia if prompt measures are not taken. Such cases are somewhat similar to those terrible cases of ulcerative colitis which are well known and dreaded by all physicians of experience.

When once it is certain that there are large chronic ulcerating surfaces in the colon, and when symptoms of toxæmia are present and do not improve under medical treatment, then surgical measures are imperative.

Reasons for Operation.

There are two purposes for which the surgeon may be asked to operate: (*a*) to provide an opening for washing out the colon from above, or (*b*) to divert the intestinal contents so as to give rest to the colon. These purposes are not necessarily mutually exclusive, but upon the main purpose depends the type of operation.

For providing means for irrigation of colon from above, appendicostomy and valvular cæcostomy are suitable. For diversion of the intestinal contents the surgeon must perform open cæcostomy or enterostomy or ileo-sigmoidostomy.

Appendicostomy has met with a considerable amount of success. The appendix is brought up to the abdominal wall, part of it is removed, but about an inch is left into which a rubber catheter is inserted, and through this the colon can be irrigated. Sometimes the appendix may be adherent, or difficult to find, or diseased, and then cæcostomy by the valvular method of Gibson is indicated. Valvular cæcostomy is probably preferable in most cases. By irrigating the colon through the opening it is possible to avoid stagnation of poisonous products with consequent toxæmia. The operation usually fulfils its purpose, though it is necessary to continue irrigation daily for months till the ulcerative surfaces have had time to heal. The condition may relapse if the opening be allowed to close too soon. It is well known that many dysenteric patients die with symptoms of toxæmia often extending over many weeks. Yet there appears great reluctance to try the simple surgical measure which at any rate *may* save the life which is failing.

Illustrative Case.

The following case illustrates well the remarkable change for the better that may happen in suitable cases.

Pte. E. L., 29 years. Admitted to 31 B.S.H., on Dec. 10th, 1917, under the care of Captain Waller, R.A.M.C. History: Slight dysenteric attacks in August and October, 1917. The present attack started in December, 1917. After admission he had four weeks' treatment with emetine. On Dec. 11th and 26th, *Entamœba histolytica* found in stools. Jan. 6th: Poor general condition. Tongue foul. Entire course of colon tender. Feb. 6th: Examination of stools negative to *E. histolytica*. Feb. 21st: There had been steady deterioration in spite of three 12-day courses of emetine. Pulse-rate 130. Stools varied between 6 and 10 per diem—nearly every one showed blood and sloughs.

On this date, on the advice of Colonel Willcox, cæcostomy (valvular) was performed. Immediate and rapid improvement occurred on beginning irrigation from above. Patient was evacuated on May 6th, 1918, having put on much weight.

No one who has seen a case like the above can doubt the efficacy of the operation in such patients. If the colon is so diseased that it is desired to prevent the fæcal contents passing through it, open cæcostomy (cæcal anus) enterostomy, or ileo-sigmoid anastomosis may be performed.

Open cæcostomy (i.e., freely opening the cæcum after attaching it to the abdominal wall) has been advocated at different times during the past 30 years, but not often practised. Herrick, however, in 1909 published an account of 11 cases all practically moribund, of which he saved 4 by an open cæcostomy.

Enterostomy has been suggested for those cases in which the cæcum is badly diseased. The only case in which I have known this to be done was under the care of Mr. McNeill Love at Amara. A cæcostomy was first performed and proved of benefit only for a short time. An abrupt relapse occurred, so an enterostomy six inches from the cæcum was performed. The lower end of the small intestine was closed. Improvement was immediate, and the patient put on 2 st. weight in six weeks. The enterostomy was closed three months after the second operation by lateral implantation into the ascending colon. In Mr. Love's opinion complete enterostomy is the best operation for chronic dysentery which does not react to treatment, for in no other way can complete rest of the colon be attained, and such rest, he thinks, is of more importance than irrigation. (Mr. Love tells me that Mr. Grey Turner suggested the idea to him.)

I cannot find any cases which have been treated by ileo-sigmoidostomy, though Carey Evans puts forward the opinion that the ideal treatment is by such an anastomosis combined with appendicostomy. But a short circuit would not divert the whole contents of the bowel as would complete enterostomy or enteric anus.

So far as the limited but collective experience enables us to judge one would conclude that for the colonic pus-sac of chronic dysentery, or for any chronic toxæmic ulcerative colitis, appendicostomy or valvular cæcostomy should first be tried, and if no improvement occurred after irrigation an open cæcostomy or, better still, enterostomy with complete division of the small gut would be advisable. Lateral anastomosis whilst the colitis was still active would hardly be a wise procedure.

(v.) *Cicatrisation and Stricture.*

It is surprising that so few cases of post-dysenteric stricture of the large bowel are on record. Perhaps it is because the milder degrees of ulceration heal without undue contraction, whilst many of those with gangrene of large portions of the mucous membrane, which would be followed by stricture,

lead to a fatal issue. On this point Sir Leonard Rogers has kindly written me. He writes:—

> "I have never seen stricture of any part of the large bowel follow dysentery, nor do I know of any such case in our museum, which dates back over 80 years and contains some five thousand specimens, including numerous dysentery ones. This is certainly rather strange in view of the extent of damage to the bowel, but may perhaps be partly explained by the more extensive lesions of amœbic dysentery being so frequently fatal in the acute stage while in the bacillary the lesions do not extend deeper than the submucous coat as a rule."

Davidson saw six cases of stricture of the colon during 30 years of experience of dysentery in India. No case of stricture was recorded in the large number of cases in the American Civil War, though we have no proof that the cases were followed through.

In text-books it is customary to describe dysenteric stricture of the rectum as if it were a fairly common occurrence, but in spite of the large numbers of cases of dysentery in the late war it is rare to find a rectal stricture resulting therefrom.

It is well recognised, however, that persons who have been the subject of severe dysentery may after complete recovery still suffer from minor derangements of the bowel. I would hazard the suggestion that some of these may be due to irregular or undue cicatrisation of the colon, if not to definite stricture.

(vi.) *Perinephric Abscess.*

It is with some hesitation that I put perinephric abscess as a complication of dysentery, but in a series of 11 perinephric abscesses (not consequent on gross disease of the kidney) which I have treated in the past two years four had a previous history of dysentery or diarrhœa. In two of these amœbic cysts were found in the fæces. The organism in the abscesses was always the staphylococcus. It is, of course, possible that the septic organism would escape through the diseased gut wall where it was unprotected by peritoneum and so cause an abscess in the loose cellular tissue round the kidney. Treatment of such abscesses by incision and drainage at the outer border of the erector spinæ is an easy and satisfactory procedure.

The remote effects of the organism or toxins are many and serious.

LESIONS CAUSED BY THE AMŒBA HISTOLYTICA.

We must first consider the lesions caused by the *Amœba histolytica*: hepatitis, liver abscess, renal abscess, cerebral abscess, splenic abscess, cystopyelitis.

Amœbic Hepatitis.

Amœbic hepatitis is a common complication of amœbic dysentery, as a rule easy to diagnose and readily amenable to treatment by emetine. Some cases are mistaken for cholecystitis and some may be confused with malarial hepatitis, but reaction to the specific treatment will soon confirm or reject the diagnosis. The symptoms are pain in the hepatic area and possibly right shoulder region, enlargement of the liver, and fever; there is usually a leucocytosis and there may be slight jaundice. A rigor may occur at the onset. The amœbæ cannot always be found in the stools at the time of the hepatitis, but usually there is a history of dysentery. The diagnosis is made sure by disappearance of the symptoms under treatment by emetine. It is possible to watch the decrease in size of the liver and the increase in movement of the diaphragm by X ray examination with the fluorescent screen. At Nasiriyah, by the courtesy of the radiologist (Captain J. L. Sen, I.M.S.), I was able to do this with advantage.

Liver Abscess.

The subject of liver abscess can no more than be touched upon in this brief review. The prevention of amœbic abscess of the liver is now a feasible project, thanks to the researches, clinical acumen, and sound judgment of a Fellow of this College (Sir L. Rogers), whose successful advocacy of the value of emetine would alone entitle him to the thanks of grateful humanity. If every case of amœbic dysentery be treated early and thoroughly by emetine, and if hepatitis be similarly treated at its inception, then surgeons will have but few liver abscesses to treat.

The early symptoms of liver abscess are those of hepatitis. In addition there is usually some congestion of the right lung base, and often wasting and anæmia. Fever is often slight and variable. The abscess may be distinguishable by X rays and may cause a swelling either of the chest wall or in the right loin or epigastrium; it may burst into the lung or some abdominal viscus. The common position of a single abscess is in the upper part of the right lobe.

In differential diagnosis one has always to bear in mind malaria, typhoid fever, paratyphoid, perinephric abscess, pleural effusion, cholecystitis; appendicitis and enlargements of the liver from other causes. Most surgeons agree that exploration by the needle is the only certain method of diagnosing the presence of an abscess.

The treatment of liver abscess is now a successful procedure. The exact method adopted varies, but there are two objects aimed at in all the methods: (1) evacuation of the abscess cavity; (2) destruction of the *Entamœba histolytica* in the walls of the abscess cavity.

The abscess may be evacuated either: (*a*) by aspiration, repeated several times if necessary; (*b*) by puncture and insertion of a small metal or rubber tube for institution of siphon drainage; (*c*) by free incision, resection of rib, and insertion of large drainage-tube.

Good results have been published by each method. I do not think that the method of evacuation matters very much so long as the amœbic infection is also dealt with. This can be done by the injection of a solution of quinine, or of emetine, into the abscess cavity; or simply by the subcutaneous or subfascial injection of emetine solution (gr. 1 daily for 10 or 14 days). I believe that it is due to simultaneous treatment by emetine that the results in drainage of liver abscess are more speedy and satisfactory. Though personally I am in favour of free drainage of liver abscess, I make the proviso that every time the surgeon dresses the case (and he should not depute the dressing save to another surgeon) aseptic precautions should be as strict as for an abdominal section. If that be insisted on and if emetine be given, I think open treatment of the abscess the most satisfactory.

When there are several abscesses in the liver the prognosis is extremely grave and surgical intervention is often if not usually unsuccessful. However, if taken in an early stage there is evidence to show that multiple liver abscesses may clear up completely under emetine (Rogers).

Unfortunately, it is not usually possible to diagnose multiple liver abscesses in the early stage. Of 16 cases of liver abscess which have come under my personal care 2 ruptured into the lung and got well under administration of emetine, 2 were treated by aspiration and injection of quinine hydrochloride into the cavity, 2 by aspiration and administration of emetine, and 10 by free drainage of the abscess combined with subcutaneous emetine. There were two deaths, one patient who had multiple abscesses and another who, after insertion of a drainage-tube, had to be dressed and nursed in a very dirty hut made of matting, and who consequently got secondary infection of the abscess. All the later cases were treated in a hospital in Bagdad, which in many respects would compare favourably with many of our hospitals in England, and where aseptic surgery could be practised with safety.

Rarer Complications.

Rarer complications of amœbic dysentery are cerebral, renal, or splenic abscesses. Abscess of the brain never occurs apart from liver abscess. Kartulis and Jacob say that it occurs in 3 per cent. of cases of liver abscess, but Legrand thinks it still less common. The abscess is usually single. The symptoms are those usually associated with brain abscess, depending for focal symptoms upon the site of the lesion. No case of this nature has come under my observation.

Still more rarely amœbic abscesses of the kidneys and spleen have been reported. Amœbæ have also been found in the urine and a cystitis and pyelitis ascribed to their pathogenic action.

SURGICAL COMPLICATIONS DUE TO BACILLARY DYSENTERY.

The remote complications of surgical interest due to bacillary dysentery are: septicæmia, arthritis, conjunctivitis, iritis, pyæmia, myalgia, fibrositis, periostitis.

Septicæmia.

This I mention first, not because it is common, but because the fact of its occurrence points the way to the cause of the other complications. Several observers have obtained *B. Shiga* from the blood. In 1918 Maer obtained a pure blood culture of the bacillus during life in a patient who had marked cerebral symptoms but no abdominal pain, straining, or tenesmus. The specific organism was not obtained from the stools, but was recovered from scrapings of the bowel mucosa after death. Waller has recorded a case in which *B. Flexner* was grown in pure culture from the blood taken shortly before death. So it is possible that many of the remote complications are due to the effect of the bacilli transported via the blood stream.

Arthritis.

Joint affections have for long been known to occur in certain dysenteric patients, but till the late war scant attention had been paid to the condition. Shiga, in his article in Osler and McCrae's System, gives but a line to arthritic symptoms. But a great mass of evidence has recently accumulated to put our knowledge on a surer foundation. Several papers on the subject have recently been written (notably one by Graham), and I can but summarise the conclusions which are agreed upon by most (if not all) observers.

Ætiology.—The lesion is generally due to the *B. Shiga* or its toxins. In most cases the fluid withdrawn from the joint is sterile, but occasionally the bacillus is recovered. Dr. William Campbell (who had a very large experience of dysentery from the time of the Dardanelles campaign till 1919) kindly informs me that he examined the fluid from 18 cases of arthritis, obtaining the *B. Shiga* from 1 case but finding the remainder sterile. It is difficult to determine whether the condition is due to a metastasis of organisms which soon die out or whether the toxins of the bacteria generally cause it. Probably the latter is nearer the truth, since it is known the *B. Shiga* produces toxins.

Time of onset.—The joint affection usually develops soon after the acute stage of dysentery is over. The day of the disease on which it appears is therefore variable. The onset is frequently associated with imperfect evacuation of the intestine. A careful observer (Captain D. W. Ritchie) writes: "Arthritis usually occurred when the cases were becoming convalescent; as a predisposing cause early constipation was an easy first, and cases treated by frequent doses of tinct. opii, which caused retention of the discharge in the bowel, were very prone to develop arthritis."

Incidence.—About 1 to 2 per cent. of cases of bacillary dysentery develop joint trouble. Waller had 6 cases among 350 patients and G. Singer 7 in 600 patients.

Severity of dysentery.—Though occurring sometimes after very acute cases, it is noteworthy that arthritis frequently developed after very mild attacks of dysentery. Occasionally it has been the development of an arthritis which has led to the discovery of a latent dysenteric infection. Colonel R. E. Kelly has kindly informed me of an epidemic of mild diarrhœa, which was followed in each case by arthritis manifestations coming on 14 to 21 days after the attack. It affected a large number of the personnel of a base hospital and from the similarity of the interval between the diarrhœa and the arthritis in each case he had no doubt that it was a specific organism causing both conditions, though cultivation proved unsuccessful.

Joints affected.—The knees and ankles most commonly, but almost any joint may be affected. Shoulders, elbows, wrists, temporo-maxillary, sterno-clavicular, and rarely the hip-joints, may suffer.

Types of joint affection.—Sometimes there is a mere arthralgia when pain is complained of, but no local sign of disease can be detected. Frequently there is considerable effusion, especially in the knees, though there is no redness or increased heat in the joint. A third and more intractable variety is that in which there is great thickening of the peri-articular structures which leads to considerable limitation of movement of the joint.

General course.—The onset is sudden, ushered in by pain in the joint often of a severe character. Effusion usually follows and the pain subsides. Fever is usually slight, though it may be more pronounced. The condition may very quickly subside, but very often lasts for two to three months, and it may be much longer before the joint recovers full function. A distinguished member of our profession who suffered severely from dysenteric arthritis in the South African War informed me that it was six months before he could walk without assistance, and much longer before he could move with any agility, and even after the lapse of so many years occasional pain and swelling in the knees occur.

Whilst in Mesopotamia I saw six cases of dysenteric arthritis in consultation with Captain Waller and several slighter cases came direct into my surgical wards. I have seen two cases since my return home, and would like to remind my hearers that a history of dysentery will now need to be inquired into in any case of arthritis.

Treatment.—The joints must be rested during the acute stage and benefit may result from counter-irritation. Firm pressure by wool and bandage or by strapping may cause the effusion to subside more quickly. Aspiration may be necessary if the effusion is great and likely to over-distend the joint ligaments. Antidysenteric serum is said by some to benefit the arthritis. After the acute symptoms have passed massage and graduated passive movement should be undertaken. In those cases with thickening round and adhesions within the joint hot-air baths, ionisation, Turkish baths, and other well-recognised methods of treating chronic joint trouble may be tried, but recovery is often slow.

Conjunctivitis and Irido-cyclitis.

One or other of these is a common accompaniment of arthritis. In Graham's series it occurred in about 50 per cent. of the arthritic cases and the same proportion is recorded by Stettner, who remarks that eye symptoms preceded the joint symptoms in one-third of the cases. The conjunctivitis is usually bilateral and clears up readily in a few days under simple treatment. The iritis may lead to adhesions, but usually subsides under treatment by atropine.

Pyæmia.—Remembering the severe ulceration often present in the colon, it is no wonder that sometimes a general septic infection occurs. I saw one patient who at autopsy was found to have streptococcal abscesses in the gall-bladder, kidney, and spleen.

ASSOCIATED DISEASES.

Associated diseases are parotitis, boils and abscesses, thrombosis (gangrene of foot, pseudo-elephantiasis of leg).

Parotitis has been mentioned by many observers as a complication of dysentery. It is an infrequent occurrence, but I had at least one case. Whether the infection gains access from the mouth or, what is quite as likely, gets there via the blood stream from the ulcerated colon we cannot determine, but the inflammation may be severe enough to cause complete necrosis of the gland. According to Shiga, it is usually bilateral and occurs from the third to the fifth week of the disease. If the general symptoms of toxæmia are serious it is essential to incise the parotid freely.

Boils and abscesses may be an accompaniment of dysentery. Shiga mentions two cases of abscess which occurred in convalescence, and Waller states that 9 patients out of 350 developed boils on the convalescence of bacillary dysentery. In one case of Shiga type 28 large boils appeared in successive crops over the buttocks, trunk, axillæ, face, and fingers, with pyrexia for 14 days. Whether the resistance to staphylococci is lowered by the disease or whether it be a case of pyæmia originating in the colon it is difficult to determine.

I wish to express my thanks to all those who so kindly placed at my disposal their valuable knowledge and experience.

THE LATE MR. D. J. WILLIAMS.—The death of David James Williams took place at his residence at Llanelly, Carmarthenshire, on Feb. 27th, at the age of 66. He received his medical education at University College, London, where later he was demonstrator of practical physiology, qualifying M.R.C.S. in 1877. In 1894 he obtained the Fellowship. He was greatly esteemed in Llanelly, where he had a large practice and was active in public affairs, being a member of the Chamber of Commerce and a medical referee under the Workmen's Compensation Act.

ST. BARTHOLOMEW'S HOSPITAL APPEAL FUND.— A successful bazaar, organised by the Women's Guild, was held in the Great Hall of the hospital on March 4th. A soiree has now been arranged for Saturday, March 20th, at 8 p.m., to be held at the Royal Albert Hall, South Kensington. The artistes appearing are: Miss Carmen Hill, Mr. Ben Davies, Mr. Ivor Foster, Miss Sybil Goodchild, Mr. Lorne Wallet, Master Napoleon Bertrand Eugene, Professor K. Ronay, and Mr. Corelli Windeatt's Orchestra of 90 performers. The hospital is issuing a pleasantly written booklet, describing hospital life from the patient's point of view, in aid of the new nurses' home.

PLEURAL EFFUSION:
ITS CYTOLOGY AND THE RESULTS OF PARACENTESIS.

BY D. S. PAGE, M.B., B.CH.CANTAB., M.R.C.S., L.R.C.P.

WHILE lymphocytic pleural effusions have for some years been regarded as usually tuberculous in origin, opinion is not unanimous as to the cause of effusions in which other cells predominate. Varying views are also held on the indications for paracentesis in tuberculous pleurisy. In the hope of aiding the elucidation of these problems this investigation was undertaken.

The statistics are taken from the notes of patients with pleural effusion who were in the Brompton Hospital for Consumption and Diseases of the Chest in the years 1911 to 1918. The series includes only effusions in which no organism other than the tubercle bacillus was demonstrated, of which there is a record of the cytology and in which the presence of red blood corpuscles is not reported. This last condition, although it seemed necessary to ensure accuracy in the cytology of the effusions, reduced very considerably the number of cases for investigation.

In all 60 cases were investigated. These were divided into six groups as follows: (*a*) 20 cases in which tubercle bacilli were demonstrated in the sputa. (*b*) 8 cases in which there was clinical evidence of pulmonary tuberculosis, but tubercle bacilli were not demonstrated in the sputa. (*c*) 22 cases in which there was no evidence of pulmonary disease. Of these most were regarded as tuberculous. (*d*) 2 cases of hydropneumothorax. (*e*) 6 cases of mediastinal neoplasm. (*f*) 2 cases associated with cardiac and renal disease respectively.

Cytology.

On the subject of cytodiagnosis in Allbutt and Rolleston's "System of Medicine"[1] it is written, "The pioneers in this work were Widal and Ravaut, who, as a result of their observations, stated the following cytological formula: When the dominant cells present in a pleural effusion are small lymphocytes the probable cause of the inflammation is the tubercle bacillus; when the dominant cells are the polymorphonuclear leucocytes the probable cause is some pyogenetic micro-organism.—If the effusion from a tuberculous pleurisy is examined very early, the predominance of the lymphocyte is less marked than as the effusion progresses. The polymorphonuclear cells may even be present in excess; Dr. Gulland considers that this is limited to the first three days of the effusion. To these original conclusions of Widal and Ravaut's little has since been added by other observers."

In the series under discussion, in only six cases were more than half the cells polymorphonuclear neutrophiles. Of these, four had tubercle bacilli in the sputa. Of the two remaining, one (Case 58) was associated with septic pneumonia in a patient with mediastinal lymphosarcoma; the other (Case 50) was regarded as of rheumatic origin. This patient, admitted with a history of pain in the joints of one week's duration, had pericarditis in addition to double pleural effusion. In the tuberculous cases the duration appears to have been, in Case 1, eight days; in the others (Cases 9, 11, and 18) probably some months. Dr. Roodhouse Gloyne considers that the predominance of the polymorphonuclear neutrophilic cell in a tuberculous pleural effusion is usually due to pneumothorax, though this may not have given rise to physical signs. The finding of tubercle bacilli in the fluid in Case 9 lends some support to this view, so far as that case is concerned; for tubercle bacilli are commonly more numerous in hydropneumothorax than in effusions not communicating with the lung. Of two cases (51 and 52) diagnosed as hydropneumothorax, tubercle bacilli were found in the effusion of one, but in both the enumeration showed a preponderance of mononuclear cells, the polymorphonuclears being 15 per cent. and 6 per cent. respectively.

Gruner states[2]: "The appearance of polynuclear cells in an exudate may be looked on as the expression of a general reaction on the part of the individual against a more severe infection. The more virulent the infection the more decided will the polynucleosis be." Three of the cases under discussion had severe general reactions. The fourth, however, in which tubercle bacilli were demonstrated in the fluid, was apyrexial throughout the period of his stay in hospital, and on discharge was sent to Frimley Sanatorium.

The remainder of the effusions of tuberculous or of unknown origin showed a predominance of small mononuclear cells, with the exception of Case 49, in which 80 per cent. of the cells were coarsely granular eosinophiles. While this patient was in hospital his blood contained at different times 5 per cent., 7 per cent., and 12 per cent. of eosinophiles. There was no history of asthma, no evidence of infection by worms, and, indeed, no reason was found for the eosinophilia. This patient was good enough to come to the hospital for examination five years later, when he appeared to be enjoying good health. His weight had increased by 13 lb. since his discharge from hospital. He had no cough nor expectoration, but complained of occasional pain in the chest. On examination no signs suggestive of pulmonary tuberculosis were found. His blood contained 6500 leucocytes per c.mm., of which 5 per cent. were coarsely granular eosinophiles.

The effusion of Case 57 contained 40 per cent. eosinophilic cells. This was from a patient who died shortly afterwards from a columnar-celled carcinoma involving the left lung and the mediastinum. In the right iliac fossa was a large cyst, behind which the ilium and sacrum were found to be eroded; sections of the cyst wall appeared to be carcinomatous. The blood of this patient contained 7 per cent. eosinophiles. No parasites nor ova were found in the stools.

The presence of these cells is recorded in only two other cases: Case 14, tuberculous, had 2 per cent., and Case 50, regarded as rheumatic in origin, had 2·5 per cent. The two cases in which eosinophilic cells predominated were probably non-tuberculous. This is in conformity with the experience of Barjon and Cade,[3] who showed by inoculation experiments that their eosinophilic effusions were not tuberculous.

Basophilic cells were reported to be present in only four cases, and in these in small numbers. The eosinophilic effusion (Case 49) contained 3·8 per cent. basophilic cells, and that of the supposedly rheumatic case (50) 1·75 per cent. In Case 60, chronic nephritis, 1 per cent. of these cells was present. The only tuberculous effusion in which basophilic cells were found contained 0·6 per cent. only of these cells. This case was 28, in which the signs of pulmonary tuberculosis were not definite. The significance of these cells is not known.

The proportion of large mononuclear cells was very variable but, except in the two cases of hydropneumothorax, in which large mononuclears formed 31 per cent. and 26 per cent. respectively of the total cells, in none of the effusions of tuberculous origin was it higher than 23 per cent. Among the growths the highest number reported for this cell was 56 per cent., and even in the case of arteriosclerosis with heart failure it was only 63 per cent.

Dr. Roodhouse Gloyne[5] considers that hydrops pleuræ of renal origin more nearly approaches the character of an exudate than that of a transudate. Only one case (No. 60) occurred in this series. In this the cells were polymorphonuclears 24 per cent., small mononuclears 55 per cent., large mononuclears 20 per cent., basophiles 1 per cent. From this patient, who was suffering from chronic interstitial nephritis, the fluid had previously been drawn off weekly for eight weeks.

In the summary of his paper on Cytodiagnosis, Athole Ross[4] states: "It will be unnecessary in future to have recourse to animal experiments to prove the existence of tuberculous pleurisy if a well-marked lymphocytosis has been obtained." It is now recognised, however, that in some effusions associated with new growths lymphocytosis is present. Of six patients in this series suffering from mediastinal growths, in three over 80 per cent. of the cells of the effusions were small mononuclears. In Case 53, lympho-sarcoma invading the left pleura, the cells in the effusion at the first examination had been: large mononuclears 56 per cent., small mononuclears 44 per cent. Three months later 96 per cent. were small mononuclears. This is a striking example of the supposed tendency in effusions for the proportion of small mononuclear cells to be progressively increased. Little evidence of this tendency is obtained from a comparison of the cytology with the duration of effusion in this series. None were examined earlier than five days from the time of onset of pleurisy. Two (Cases 14 and 26) were examined on the fifth day; they contained 68 per cent. and 58 per cent. respectively of small mononuclear cells. In Case 34, aspirated on the tenth day, 92 per cent. of these cells were found, but in cases of much longer duration the predominance of the small mononuclear was frequently less.

Results of Paracentesis.

In Allbutt and Rolleston's "System of Medicine" (1909) it is recommended that in pleural effusions complicating pulmonary tuberculosis paracentesis should be avoided, unless the quantity of fluid be so great as to cause embarrassment of the respiration. In uncomplicated pleural effusion, paracentesis should be performed in all cases presenting an effusion so great as to fill the pleura; in those attended by any distress of breathing, and in those showing no signs of absorption after a week or ten days of treatment by drugs. The treatment of primary tuberculous effusions has tended recently to become more conservative. Rest of a part of the body affected by tuberculosis has been found useful in other regions, notably in the joints; it is reasonable to expect it to be beneficial in pleurisy. In addition to this, the opinion has gained ground that some constituent of the fluid is useful in combating the disease. Gilbert of Geneva, in 1896, advocated the withdrawal of a small amount of fluid from the pleural cavity and the inoculation of 2 c.cm. into the patient's own subcutaneous tissue. A. Jousset, in 1912, recommended

Explanation of Tables.

P, neutrophilic polymorphonuclear cell.

S, small mononuclear cell.

L, large mononuclear cell; includes the large lymphocyte and the endothelial cell.

E, coarsely granular eosinophilic cell.

B, basophilic cell. The numbers of cells are percentages.

Paracentesis +, paracentesis performed.

Paracentesis 0, paracentesis not performed. In these cases a small quantity of fluid was removed for examination.

T.B. +, tubercle bacilli demonstrated.

T.B. 0, tubercle bacilli not demonstrated.

The duration of an effusion before examination is inferred from the history of the patient. In many cases its accuracy is not certain.

Temperature + signifies temperature above 98·6° F.

,, – ,, ,, not above 98·6° F.

C.P.T. signifies chronic pulmonary tuberculosis.

TABLE V.—*Six Cases of Mediastinal Neoplasm.*

Note.—The death in Group B was from acute tuberculosis; the peritoneum was involved as well as the pleura. Several cases in Group A had extensive and active pulmonary disease at the time of aspiration.

taking the serum from the effusion of a patient suffering from acute serofibrinous pleurisy and injecting it subcutaneously into cases of chronic tuberculous pleurisy. Heteroserotherapy has been used at Frimley Sanatorium[6] in a small series of advanced cases of pulmonary tuberculosis. In order to avoid the loss of constituents of the effusion or their destruction by heat the pleural fluid for the injection was citrated, and its sterilisation was effected by carbolic acid. The results were encouraging.

The writer has been unable to discover any published statistics on the immunity reactions of tuberculous pleural effusions (see note at end). In 1911, at the Brompton Hospital, the tuberculo-opsonic index was worked out in a small series of pleural effusions; the results are given in Table IX. In the majority of tuberculous cases the opsonic index of the fluid was lower than that of the blood. Of those in which the index was higher in the fluid, two cases were recent and a third had been aspirated three days previously. These figures suggest that a recent tuberculous pleural effusion may be rich in antibodies, and that these may be lost to a large extent in the course of time.

TABLE IX.—*The Tuberculo-opsonic Index of 18 Pleural Effusions.*

Remarks.—9. Recent. 12. Autopsy held. 15. Autopsy held. 17. Fluid aspirated also four months previously. 18. Specimen of effusion obtained 14 hours after death.

An attempt was made to discover the effects of paracentesis from a study of the notes of the series of cases of which the cytology has already been discussed. Points especially looked for were changes in the temperature, pulse-rate, and weight of the patient; his condition on discharge from hospital was noted.

Effect on Temperature, Pulse-rate, and Body-weight.

In the majority of cases little or no alteration in the temperature chart occurred as the result of paracentesis. In most cases pyrexia was of two or three months' duration, whether the fluid had been withdrawn or not. In one (Case 35) a high temperature was recorded for nine months after aspiration. A fall in temperature following the withdrawal of fluid occurred in a few instances, the most striking being Cases 15 and 33. In the former it fell to 98·6° a few hours after aspiration, in the latter to 99° on the day following it, in both remaining about normal. In Cases 34 and 43, where there was a gradual fall of temperature after aspiration, the patients had been in hospital only two days before the removal of fluid; the fall in temperature may well have been due to causes other than paracentesis. In six other charts, all from cases complicated by pulmonary tuberculosis, a gradual fall of temperature was noticed, but in these a slight fall had occurred before the operation.

In 11 cases there was some rise of temperature; in three on the day only on which the pleura was punctured; in six on the following day; while in Case 8, extensive pulmonary and intestinal tuberculosis, the pyrexia continued for five days, and in Case 50, probably rheumatic, for 12 days. It is probable that the rise of temperature on the same evening is often due to a nervous cause, but the other cases may be instances of auto-intoxication, of which Dr. M. Paterson[7] states there is a danger in aspirating tuberculous pleural effusions. A similar rise of temperature, lasting one, two, and ten days respectively, occurred in three of the cases associated with growths; in these, too, it may possibly have been due to the absorption of toxins.

Pulse-rates were very variable both before and after paracentesis; no change in rate could be definitely ascribed to the operation.

In most cases the weight of the patient seemed not to be affected (beyond that resulting from the loss of fluid). In Cases 31 and 45, both uncomplicated by pulmonary tuberculosis, the patients, who had been gaining weight before, began to lose it again about the time of aspiration. In no case did a gain in weight seem clearly attributable to paracentesis.

The condition on discharge from hospital, so far as it can be summarised for each patient in one word, is shown in the tables. It shows little difference between the condition of patients on whom paracentesis had been performed and those on whom it had not been performed. No complications resulting from paracentesis, such as hæmorrhage, pneumothorax, and serous expectoration occurred, nor were any cases of sudden death noted.

Summary.

The small number of the cases investigated, and their variability in relation to both cytology and results of paracentesis, make it impossible to draw any conclusions. The following points, however, are suggested or emphasised:—

1. A predominance of polymorphonuclear neutrophilic cells occurs not uncommonly in chronic pleural effusion complicating pulmonary tuberculosis. When it occurs, in the absence of secondary infection of the fluid, it suggests the possibility of hydropneumothorax being present; probably it may occur without this complication as the result of a virulent tuberculous infection.

2. A predominance of small mononuclear cells is usual in tuberculous pleural effusions. It is not uncommon in effusions associated with neoplasms. It may occur in renal cases.

3. Effusions in which coarsely granular eosinophilic cells are found in large numbers are probably not tuberculous.

4. Basophilic cells occur rarely, and only in small numbers.

On theoretical grounds it seems better to reserve paracentesis for the relief of urgent symptoms. In the analysis of this series of cases no clear evidence is obtained either in favour of or against paracentesis.

For permission to use the pathological records I am indebted to Dr. A. C. Inman, superintendent of the laboratories at Brompton Hospital. To him and to Dr. Roodhouse Gloyne, pathologist to the City of London Hospital for Diseases of the Chest, my thanks are due for suggestions and advice.

Note.—Since the above was written my attention has been drawn to two reports on immunity reactions obtained in small numbers of tuberculous pleural effusions. In one[8] the complement-fixation test for tuberculosis was done on the sera of four primary pleural effusions in which there was cytological evidence of tuberculosis. The results were positive in all cases. The blood serums of these patients were negative in two cases; in the other two positive, but less strongly so than those in the effusions. In the other[9] the precipitin reaction for tuberculosis was done on 22 cases with the following results:—

In 4 known tuberculous cases reaction was … … … … … … … …	positive in 3. negative in 1.
In 14 probably tuberculous cases reaction was … … … … … …	positive in 5. doubtful in 2. negative in 7.

In 4 non-tuberculous controls reaction was negative in 4.

THE PERIODICITY OF INFLUENZA.

BY B. E. SPEAR, F.S.S.

TWO articles have recently appeared in THE LANCET dealing with the periodicity of influenza epidemics. In the first article Dr. John Brownlee (Nov. 8th, 1919, p. 856) stated that he had deduced from analysis of influenza mortality, by the method of the periodogram, that epidemics recurred in 33-week periods; and he was thus led to forecast an epidemic at the end of January or in February of this year. Dr. C. O. Stallybrass, in the issue of Feb. 14th, finds exemplification of Dr. Brownlee's conclusions in the Liverpool experience since 1890, and, in addition, evidence therein of different strains of influenza bacilli with varying periodicity.

The method of analysis upon which Dr. Brownlee relies can, however, only yield correct results when the data to which it is applied can be described as recurring "waves" of approximately *uniform* "amplitude"; and data conforming to this requirement are practically non-existent in vital statistics. No more unsuitable material for analysis by the periodogram method could have been selected than the highly fluctuating figures of influenza mortality; and, as will be shown, the periodicity of 33 weeks of Dr. Brownlee has no existence in fact.

The weekly deaths in London from influenza for 1890–1919 (the period to which Dr. Stallybrass refers) are readily accessible, being contained in the weekly returns of the Registrar-General for those years, and will serve to illustrate the facts. They are not likely to differ in any material degree from the Liverpool records. The influenza prevalences are readily located, and the week of maximum mortality noted.

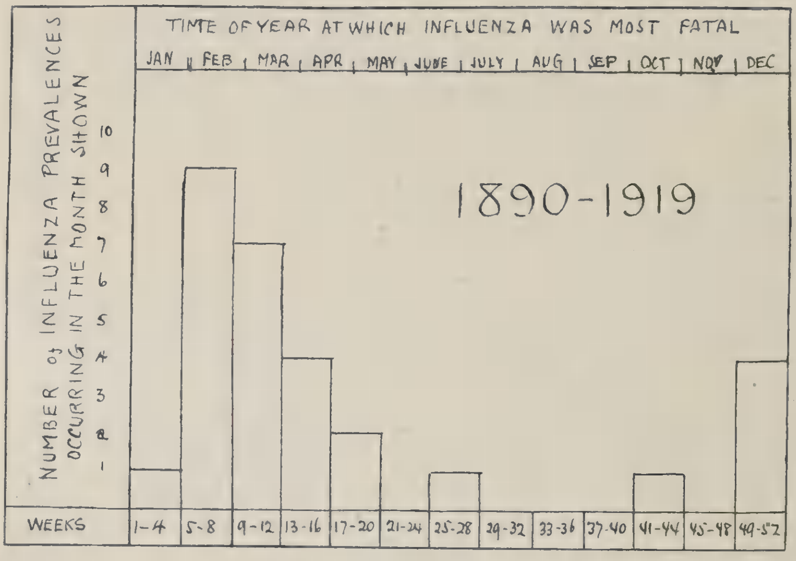
Tests of Periodicity.

Two simple tests have been applied to demonstrate the existence or non-existence of periodicity.

1. The year being divided into 13 four-weekly periods, the frequency with which the observed week of maximum mortality falls into one or other of the 13 groups has been tabulated. The result is shown graphically in Fig. 1. It will be seen that the climax of an influenza prevalence falls more frequently in the second and third four-weekly period than in others—i.e., the months of February and March. If there had been a periodicity of 33 weeks there would have been an equal number of these climaxes in each of the 13 divisions of the year. This test shows, therefore, that there is no period of 33 weeks, but that there is an approximation to a seasonal or annual period; and that the time mentioned by Dr. Brownlee in his forecast—the end of January or in February—is in any year the most likely time for an influenza prevalence.

2. The interval of time by which successive climaxes are separated would, if there were a periodicity of 33 weeks, on an average approximate to this period. There were, in the 30 years 1890–1919, 32 of these climaxes or "peaks" in the influenza mortality; and the frequency of intervals of different lengths which separate adjacent "peaks" is graphically illustrated in Fig. 2.

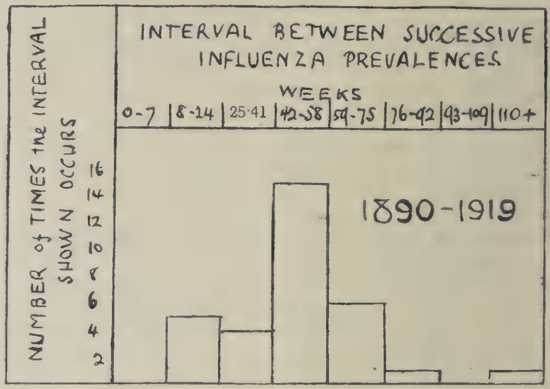
FIG. 1.



It is clear that, were there any periodicity of 33 weeks, there would be a large number of instances in which the interval would fall in the group containing intervals of 25–41 weeks, to which 33 weeks is central. The graph shows, in fact, that a far greater number belong to the group which contains the solar year.

Both tests thus demonstrate the non-existence of the 33-week periodicity.

FIG. 2.



How then is the result found by Dr. Brownlee by the periodogram method to be accounted for? The explanation lies in the fact that the "amplitudes" of the successive "waves" of influenza mortality—the number of deaths during the week of climax—in certain of the epidemics in this period are so great as to overshadow, and practically to eliminate, the smaller outbreaks when the data are subjected to analysis by the periodogram method. In the series of years 1890–99, to which Dr. Stallybrass refers as specifically illustrative of the 33-week periodicity, the mortality in the third week of 1892 (506 deaths), the twentieth week of 1891 (319 deaths), and the tenth week of 1895 (473 deaths) overshadowed all the other climaxes. The distances between these epidemics were 35 and 99 weeks respectively; and obviously if the series of years be cut up into periods of 33 weeks the mass of the 1891, 1892, and 1895 epidemics will fall into approximately the same relative position in the particular 33-week section to which each belongs. Hence the high "amplitude" obtained by Dr. Brownlee for this *spurious* period.

The interval between the two epidemics of 1918 in New York was 30 weeks; in Gothenburg only 10 weeks. Between these two extremes all kinds of intervals occurred in other towns.

In conclusion, it may be added that while no differentiation has been made above between the influenza mortality of pandemic years and intercurrent prevalences, it is believed that the causation of the two types is different; nevertheless, so far as periodicity is concerned, if regard be limited to the influenza pandemics of 1890–95, 1899–1900, 1908–09, and 1918–19 the average interval is 50 weeks—i.e., about a year.

THE LATE DR. J. REES GABE.—John Rees Gabe, who died at his residence in Mecklenburg-square, London, on March 2nd, in his sixty-eighth year, was a student at the London Hospital and became L.S.A. in 1876, taking the M.R.C.S. Eng. three years later. After holding a junior appointment at the Poplar Hospital he was for two years clinical assistant at the London Hospital, and afterwards at the Hospital for Sick Children, Great Ormond-street. In 1885 he passed the M.D. Brux. examination with distinction, and became later president of the Brussels Medical Graduates' Association. Dr. Gabe held the posts of physician to the London Dispensary, to the General Post Office, Mount Pleasant, and to the National Society for the Prevention of Cruelty to Children. He was also public vaccinator for Holborn and divisional surgeon to the Metropolitan Police.

A NOTE ON THE USE OF UNIVALENT SERUM IN THE TREATMENT OF CEREBRO-SPINAL FEVER.

BY H. STANLEY BANKS, M.A., M.B., CH.B., D.P.H.,
MEDICAL OFFICER OF HEALTH, MOTHERWELL; MEDICAL SUPERINTENDENT, BURGH HOSPITAL, MOTHERWELL; LATE BACTERIOLOGIST, B.E.F., SALONIKA.

THE ease of diagnosis of the type organism of cerebro-spinal fever by simple and rapid laboratory methods and the remarkable possibilities of cure in the treatment of this disease by antimeningococcic type serum are not yet as widely known as they deserve to be. Reference to Case 2 described hereunder will, I think, show that, at least as regards type 1 of the disease, there is some justification for the hope that it is on these lines that treatment of cerebro-spinal fever is likely to meet with successful results. This article refers more particularly to the first of the four types described by Gordon.

Gordon's Four Types of Meningococcus.

Among the advances made by medical science during the war not the least important is Gordon's discovery of the four types of the meningococcus. Formerly we were content to classify the cases clinically as "fulminating," "acute," and "subacute" or "chronic." Now we have a bacteriological classification of the disease into cerebro-spinal fever types 1, 2, 3, and 4, and with a little more experience a fairly reliable clinical classification corresponding to these types may also be arrived at.

A few observations on this point have already been made. Thus Kennedy and Worster Drought[1] investigated the relation of the type of meningococcus to the clinical picture in 22 cases and found that 8 cases infected with Gordon's type 1 were all gravely ill, with a fatal issue in 6 cases; that of 6 cases with type 3 some were severe and some moderately severe, and that the 8 cases of type 2 all recovered; of type 4 there were no cases recorded. The observations suggest that types 1 and 3 (Nicolle type A) are more virulent as regards the meninges, and that types 2 and 4 (Nicolle type B or parameningococcus) are specially prone to cause septicæmia and extrameningeal metastases.

The evidence of other writers, such as Rolleston[2] and Adshead,[3] on the point is more conflicting and no constant relationship can be regarded as established.

The process of differentiation of the type is similar to what is already fairly well established for the enterica group of fevers—viz., typhoid, paratyphoid A, and paratyphoid B, in each of which a distinctive clinical picture is frequently obtained enabling a presumptive clinical differentiation to be made. The same can be said of the dysenterica group of bacillary dysenteries.

In the cerebro-spinal group of fevers, however, the differentiation is of vastly greater practical importance to the patient, for upon it rests the question of specific treatment by the univalent type serum, and this is prima facie the only treatment which affords a substantial prospect of success.

Illustrative Cases.

The following two cases illustrate the results which may be obtained in type 1 cerebro-spinal fever by the intrathecal injection of the specific type 1 serum. In the first case I came to the diagnosis slowly by a process of exclusion. In the second case, profiting by experience, I made the diagnosis directly on clinical grounds, and confirmed it a few hours later by a simple bacteriological agglutination test. In this latter case a single intrathecal injection of the type 1 serum cut short well-advanced cerebro-spinal fever in a single night—a rapidity of cure which I have never seen surpassed by any form of antitoxin treatment.

CASE 1.—A boy (T. J.), aged 4 years and 7 months, was admitted to the Burgh Hospital, Motherwell, on July 11th, 1919, suffering from cerebro-spinal fever of 14 days' duration.

History: Vomiting at onset and subsequently at intervals; pyrexia each day; gradually increasing retraction of head. On admission the boy was thin, fretful, and looked ill; considerable retraction of head and rigidity of muscles of back of neck; Kernig's sign positive. Tâche cérébrale present. Pupils equal and normal. No eruption. Lumbar puncture produced about 30 c.cm. turbid cerebro-spinal fluid under pressure. Microscopical examination showed numerous polymorphs and typical Gram-negative intracellular diplococci.

Course of the disease.—This can be followed by reference to Chart I. My laboratory was not in working order at the time, and I conveyed the cerebro-spinal fluid for examination to Dr. W. R. Wiseman, of the Glasgow Municipal Laboratory. The meningococcus was grown by Dr. Wiseman, and types 3 and 4 excluded by agglutination tests. Unfortunately, he was unable to obtain agglutinating serum for types 1 and 2, and he reported that presumably the organism belonged to one of the latter types. I had meanwhile given empirically one dose of multivalent serum and two doses of type 2 serum intrathecally, but absolutely without result. Assuming, therefore, that I was dealing with type 1 of the disease I gave 25 c.cm. (Lister Institute) type 1 serum intrathecally on July 24th. By this time the child was in the twenty-seventh day of disease. He could not have weighed more than 10 lb., was horribly emaciated, and in extremis. Nevertheless, he improved visibly the following day. I repeated the injection two days later, and his temperature became normal on the following day and general improvement set in. On July 30th I gave 25 c.cm. (R.A.M. College) type 1 serum, and this, unfortunately, was followed by symptoms which were possibly anaphylactic in character—pyrexia, purpura hæmorrhagica, black stools, and retraction of head. The child was extremely feeble, and I think I have never seen anyone so ill as he was then recover. Improvement set in again on August 17th, when he began to talk and take notice. He was eventually discharged, physically in splendid condition and mentally bright, alert, and intelligent on Nov. 18th. Lumbar puncture was in this case carried out 20 times between July 11th and August 16th, by which time the cerebro-spinal fluid was perfectly clear.

The diagnosis in the above case was strongly presumptive of type 1, both from bacteriological findings and the results of the treatment. The next case provides a striking similarity as regards symptoms and a strong contrast in diagnosis, treatment, and course.

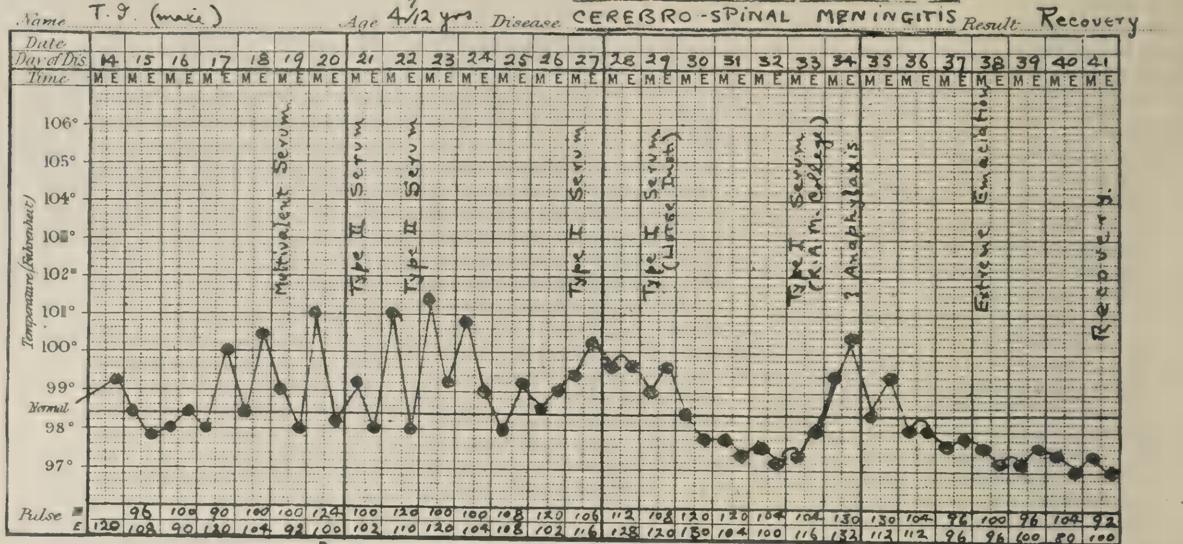
CASE 2.—A male child (J. McD.), aged 1 year and 3 months, was admitted to the Burgh Hospital, Motherwell, on Nov. 20th (the thirteenth day of illness) suffering from cerebro-spinal fever.

History: Vomiting at onset; pyrexia each time examined; gradually increasing retraction of head. On admission the child was pale, wasted, very cross, and peevish; well-marked retraction of head. Tâche cérébrale present; Kernig's sign doubtful. Pupils normal and equal. No eruption. Lumbar puncture confirmed the diagnosis of cerebro-spinal fever.

Cultural and agglutination tests.—A meningococcus was grown which was agglutinated strongly by type 1 serum and not at all by types 2, 3, and 4 (R.A.M. College) or by normal human blood serum.

Treatment and course.—(See Chart II.) Patient's temperature on admission was 102° F. and lumbar puncture

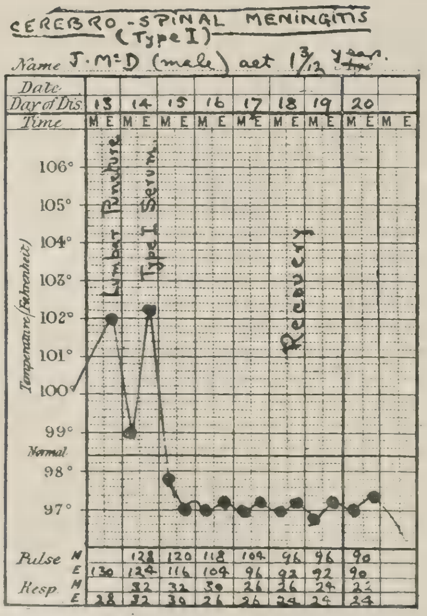
CHART I.



Type 1 disease not diagnosed until twenty-seventh day, by which time the child was desperately ill. Note favourable effect of two doses type 1 (Lister Institute) serum. Further injection of type 1 serum (R.A.M. Coll.) followed by severe symptoms, possibly anaphylactic in character. Extreme emaciation; gradual recovery. Note uselessness of multivalent and type 2 serum in this case.

gave about 25 c.cm. turbid fluid under pressure; this fluid was cultured. The following evening the temperature was 102·2° and lumbar puncture gave about 10 c.cm. turbid fluid. The similarity of his symptoms to those of Case 1 induced me to give an intrathecal injection of 20 c.cm. (Lister Institute) type 1 serum.

CHART II.



C.-S.M. Type 1. Admitted on thirteenth day of disease. Lumbar puncture yielded 30 c.cm. turbid fluid. Type 1 serum injected on following evening. Note fall of temperature by crisis and complete arrest of the disease.

(A few drops of the serum were saved for agglutination tests.) The temperature fell by crisis the following day, and the child appeared well in the morning and was actually sitting up and moving about his cot. He was up and toddling about the ward within two days of the injection: perfectly well; appetite was voracious and sleep at night sound. He was discharged on Dec. 2nd.

The diagnosis of the type in this case was confirmed a few hours after the injection had been given by microscopic agglutination tests of the meningococcus obtained from the fluid against the type 1 serum injected, and subsequently against all four types of (R.A.M. College) serum as given in the table. The results were definite and unmistakable. They appear to show that all that is necessary in practice is to test the organism isolated against a low dilution (e.g., 1:30) of each of the type serums, provided the latter are of high titre. The reacting serum gives the diagnosis of type.

Agglutination Tests (Microscopic Method).

Organism: Meningococcus cultivated from cerebrospinal fluid of Case 2.

Serum.	Dilution.	Result.	
		1 hour.	24 hours.
Antimeningococcus univalent:			
Type 1 (Lister Institute)	1 : 30	+ + +	+ + +
Type 1 (R.A.M.C.) titre 1 : 800	1 : 30 1 : 80 1 : 160 1 : 400 1 : 800	+ + + + + +	+ + + + + + + + + +
Type 2 (R.A.M.C.) titre 1 : 800	1 : 30	–	–
Type 3 (R.A.M.C.) titre 1 : 800	1 : 30	–	–
Type 4 (R.A.M.C.) titre 1 : 800	1 : 30	–	–
Normal human blood (H.S.B.)	1 : 30	–	–

Plus signs denote clumping and cessation of Brownian movement: + + + very marked, + + marked, + distinct.

If group agglutinins are present in the non-reacting serums they do not appear to be sufficiently strong to vitiate the test.

Bacteriological Technique Required.

The bacteriological technique and apparatus required is simple. The tests can be readily carried out in any fever hospital or other laboratory which is equipped for the examination of throat swabs for diphtheria.

The culture of the meningococcus from cerebro-spinal fluid is supposed to require special protein-enriched culture media from which plate cultures must be made. In the above case I obtained copious primary growths within 24 hours on ordinary coagulated blood serum slopes, such as are used for the culture of the diphtheria bacillus from swabs. The following conditions should, however, be observed: (1) the cerebro spinal fluid should not be allowed to become chilled before the culture tubes are inoculated; (2) the culture tubes should preferably be inoculated and incubated within ten minutes of the removal of the cerebro-spinal fluid from the body; (3) the culture tubes should be warmed to blood heat before the inoculation by placing them in warm water.

The agglutination of the meningococcus for practical test purposes, given a high-titre serum, does not seem to require the elaborate apparatus usually described, such as a water-bath regulated to 55° C. and the various tubes, pipettes, and racks required for the macroscopic method. The ordinary microscopic method, as used in the old Widal test, appears to be good enough. The dilutions can be made with sufficient accuracy by the platinum loop method. A dilution of 1 in 10 is obtained by mixing one loopful of serum with nine loopfuls of normal saline. By adding to one loopful of this dilution two loopfuls of the meningococcal emulsion on a cover-glass the organisms are suspended in a dilution of 1 in 30 of the ordinary serum. The cover-glass is inverted over the ordinary "cavity" slide, and the preparation kept in the incubator at 37° C. and examined after one hour. With a high-titre serum—say, a titre of 1 : 800—clumping of the organism and cessation of Brownian movement is well marked within that time in the case of the appropriate type serum; while in the case of the other type serums or a normal serum control the test is quite negative.

Remarks.

In view of the practical importance of the subject matter of this article, I have considered it advisable to publish this preliminary communication without waiting for confirmation from a large series of cases. The method of diagnosis and treatment described can be carried out in nearly every fever hospital in the country with the minimum trouble, and possibly with great saving of life.

Supplies of type antimeningococcic serum do not appear to be yet available in the ordinary market. I obtained phials of the serum for treatment from the Lister Institute, London, and small phials for agglutination purposes from R.A.M. College, London.

BRIGHTON AND INDIAN WAR MEMORIAL.—As the contribution guaranteed by the Indian Government is limited to £4000, the original proposal at Brighton by Indians to offer to the corporation a "rest-house" as a memorial of their gratitude for the hospitality shown by the inhabitants of Brighton to the wounded Indian soldiers at the Royal Pavilion Hospital cannot be carried out. As an alternative, however, Sir John Otter, chairman of the Indian Memorial Committee, who has plenary authority to settle the matter, has offered to erect a memorial gateway and screen at the southern entrance of the Royal Pavilion and the corporation has accepted it.

NOTES ON THE
ÆTIOLOGY OF EFFORT SYNDROME.

BY R. GORDON BARLOW, M.D. LIVERP.,
LATE TEMPORARY CAPTAIN, R.A.M.C., WESTERN COMMAND HEART CENTRE.

THOSE who are acquainted with the Medical Research Committee's "Reports upon Soldiers Returned as Cases of Disordered Action of the Heart (D.A.H.), or Valvular Disease of the Heart (V.D.H.)," and with "The Soldier's Heart and the Effort Syndrome," by Dr. Thomas Lewis, may consider that there is little profit in putting forward further statistics and observations on this subject. Experience seems to indicate, however, that a large number of the members of the profession are still unacquainted with the results of the investigations that have been made at the Military Heart Centres, and the number of soldiers contained in these groups of "heart cases" is so large that the study of a new set of cases with a view to arriving at the truth regarding the ætiology of the conditions, and drawing what conclusions one may for prevention and treatment, seems amply justified.

It was estimated that at least 70,000 soldiers reporting sick had been classified as cardio-vascular cases up to the end of May, 1918, and a steady stream has continued to pass through the hospitals since then. The majority of these cases falls into the group D.A.H. or "effort syndrome." Besides the military cases there are, no doubt, considerable numbers of persons suffering from this condition who have not come under observation in the army, as the condition is by no means peculiar to soldiers.

The impressions given below are based on over 1200 cases. The figures are the result of the analysis of the records of 382 consecutive cases, all of which were ultimately classified as D.A.H., though many of them had been marked V.D.H. at some period of their military career.

Method of Investigation.

A short explanation of the method of investigation into the ætiology is necessary.

Every patient was carefully questioned regarding his health from earliest childhood. After being given an opportunity of volunteering information, he was asked directly if he had had any of the common illnesses (mentioned by name) at any time in his life. He was then questioned as to his ability to play football and other boys' games, and the character of his civil employment and his habits with regard to exercise between school and enlistment were noted. Record was made of the category in which he joined and of any previous rejection for the navy or army. A statement of the nature of the training received before proceeding on service was obtained, and direct questions were asked as to the severity of the physical drills and route marching. By this means a fairly accurate estimate of each man's capacity for exercise was made. Of course, the evidence thus elicited rested entirely on the patients' statements, but there rarely seemed any reason to doubt them, and what errors there may have been in the histories were due rather to want of recollection than to intentional suppression of facts or false statements.

In a few cases there was documentary evidence of the existence of tachycardia or other signs of abnormality of function of the cardio-vascular system on enlistment.

When with nothing to suggest that any degree of effort syndrome existed before they went on service men developed the condition later, careful inquiry was made as to the date and circumstances under which the symptoms first made their appearance, and for any illness or other casualty that could reasonably be considered as causal.

Investigating along these lines, it was found that more than half the patients had a greater or lesser limitation of power of responding to exercise before going on active service. Many of them could trace this condition to some definite illness, generally in childhood, and a considerable number of them had been told that they had "weak hearts," and had been advised to avoid all forms of strenuous exertion. The majority of these men were taken into the army in low categories and remained on the lighter forms of duty, though a few had been graded up and had carried on with heavy work for varying periods, ultimately breaking down as the result of the supervention of some infection such as trench fever, malaria, or sand-fly fever.

As nearly all the cases under consideration were examined after the cessation of hostilities, and many of them were youths who had seen no fighting and had done little strenuous training, the importance of the recognition of the "constitutional" origin of so many of these cases is obvious.

Classification of Cases.

For purposes of classification the cases have been divided into two groups:—

Group 1, *constitutional*, with history of the existence of the condition before enlistment or on commencement of physical training.

Group 2, *acquired*, with symptoms developing after a fair period of training well tolerated, or of heavy work performed without distress.

Of the 382 cases analysed, 196 fell into Group 1 and 186 into Group 2. No definite origin could be traced in 102 of the former; 47 were ascribed to rheumatic infections, comprising acute articular rheumatism, chorea, and severe recurrent sore-throat; 43 dated from various other infections; and in 4 cases the condition appeared to be merely part of a well-marked constitutional neurosis.

It will be observed that nearly one-quarter of the cases was attributed to rheumatic infection, and it should be understood that a mere statement by the patient that he had had "rheumatism" was not considered as sufficient to warrant inclusion in this class, only cases which, upon inquiry, appeared to be of true rheumatic infection being included. Pulmonary and pleural diseases formed a large part of the "other infections."

In Group 2 a more detailed analysis was possible, and, for convenience, the results have been put into the form of a table, thus:—

Analysis of Group 2.

Sub-group.	No. of cases.	Percentage.
Rheumatic infections	7	3·76
Pulmonary infections	16	8·60
Influenza	29	15·59
P.U.O. and trench fever	17	9·15
Gastro-intestinal infections	17	9·15
Malaria	12	6·45
Shell-gas poisoning	19	10·20
Wounds	10	5·38
Nephritis	1	0·54
Other infections	14	7·52
Neurotic	5	2·69
Undiscovered origin	39	20·97
	186	100·00

It will be seen from this table that the origin of the effort syndrome was traceable directly to infection of one kind or another in by far the majority of the cases, and also that rheumatic infection was a comparatively rare cause in the acquired type. On the other hand, influenza was a fairly common cause, and many of the most typical cases were to be found in this group.

Most of the wounds that were regarded as producing effort syndrome were ordinary flesh wounds of slight or moderate degree; none had been severe, but all entailed a fairly considerable period of hospital treatment and light duty, as did also the cases of shell-gas poisoning, a point of importance in the ætiology of this condition of effort syndrome which will be referred to later.

The gastro-intestinal cases consisted chiefly of patients whose D.A.H. symptoms dated from dysentery or "clinical dysentery," but there were two cases of appendicitis, one of the chronic variety in which the effort syndrome cleared up soon after the operation for removal of the appendix, and the other following drainage of an appendix abscess.

One of the five cases classed as "neurotic" was an orderly in a home hospital who had suffered for some months from chronic rhinitis, and attributed his D.A.H. symptoms to this affection combined with a long period of night duty. He was very depressed, became tearful without occasion, did not associate with the other patients or take part in the recreations of the hospital, and complained of terrifying dreams and fear of darkness; in addition, he suffered from præcordial pain and developed breathlessness and tachycardia on slight exertion. He had nothing in his history to suggest that either condition existed before enlistment. In the other four cases the condition dated from being blown up, or buried, or under heavy bombardment.

Effort Syndrome not a Functional Neurosis.

It has been suggested that the effort syndrome ought to be regarded as a condition of functional neurosis. There certainly is a neurotic element about a great many of the patients, as judged by such signs as exaggerated tendon reflexes, muscular tremors and blepharospasm, and such symptoms as subjective pains, local hyperæsthesia and hyperalgesia, terrifying dreams, fear of darkness and loneliness, fits of depression and emotional outbursts, and impairment of memory. No fewer than 89 of the 382 cases under review admitted that they were subject to terrifying dreams. Of this number 51 had dreams of falling. Marked exaggeration of knee-jerks and coarse muscular tremors were frequently met with, and complaints of severe joint pains were often made in cases in which no signs of disease or only slight rheumatoid changes could be detected. Two patients had hysterical fits, but no patient had paralysis of any sort or anæsthetic areas.

In spite of the presence of neurotic manifestations in so many of these cases it does not seem right to regard the effort syndrome as a neurosis. In the first place, no ground for classifying them as neurotic was found in more than three-quarters of the cases. Secondly, some degree of hypersensitiveness of the nervous system was so common among soldiers of all classes (as was only to be expected) that it can scarcely be looked upon as abnormal. During the period of active warfare it was a very common experience in both medical and surgical wards to hear men shouting in their sleep in a way that clearly showed they were dreaming of terrifying incidents, and a very large number of the patients were to be found grinding their teeth incessantly during sleep. Again, soldiers have been notoriously bad subjects for anæsthesia, mainly on account of their tendency to violent excitement during induction. Such disturbances as are indicated by these signs might well be expected to lead to a magnification of subjective symptoms; this was met with in many of the conditions seen in military hospitals, as, for example, in the persistent pains of trench fever, myalgia, rheumatoid arthritis, and the scars of some gunshot wounds, as well as in the præcordial pain, tachycardia, and dyspnœa of D.A.H. Yet no one would go so far as to dismiss these other conditions as purely neurotic, so that there is no justification for relegating the effort syndrome to that scrap-heap.

It is generally admitted that excessive smoking has a deleterious effect on the heart's functions, and many medical officers have expressed a firm belief that this has been the cause of D.A.H. in the majority of soldiers suffering from the condition. A diagnosis of "smoker's heart" is also very popular in the irritable heart of civil practice, both with the profession and with the laity. Probably no one will deny that army life has led to a considerable increase in the amount of smoking, but it is common experience that an active outdoor life greatly increases a man's tolerance for tobacco, because it induces rapid elimination of the toxin, so that the clerk who found five cigarettes a day quite enough for him when engaged on his sedentary work could smoke 15 or 20 without feeling any ill-effects whatever whilst on active service. At the Heart Centres every patient was asked how much tobacco he habitually used, and, as it was recognised that there is always a tendency to under-estimate one's consumption, the largest quantity to which the man could be persuaded to admit was recorded as his average. The figures thus obtained showed that excessive smoking was rare, the average in the majority of cases being from six to eight cigarettes daily. Quite a considerable number of patients never smoked or had given up the habit for a long time. Observation of the patients under various conditions at all times of the day gave no reason to doubt their statements in this connexion, and there seems no justification for the view that attributes a main part to tobacco in the production of the effort syndrome. On the other hand, many patients admitted that they found their symptoms were increased by heavy smoking after they had once been established, and some had cut down their tobacco, a course that resulted in some mitigation of symptoms in some cases.

Infection as Principal Cause of Effort Syndrome.

Turning again to a general consideration of the evidence provided by the case-records, it seems quite clear that the principal cause of effort syndrome is infection. Though rheumatic infection predominated in the "constitutional" cases, almost any infection may produce the condition. Symptoms usually made themselves felt after convalescence started, and usually resulted in the patient returning to bed or at least refraining from any form of exercise. This is a point of the greatest importance. Anyone who has just suffered from an acute toxic state is liable to experience limitation of function of all the structures that have suffered in the general poisoning, and this limitation is likely to persist if these structures are not toned up to their normal state by judicious exercise. The old bogey that every heart condition must be treated by rest in bed has led to the adoption of this line of treatment in many cases where symptoms are referred to that organ on slender grounds, with unfortunate results for the patient. Numerous patients stated that, having reported that they had slight pain in the heart region, or giddiness, or felt their heart "bumping" when they first began to get about after an acute illness, they were examined and told they had heart trouble, and were then sent back to bed for several weeks. These men usually found that their symptoms were worse rather than better when they eventually started to get about again, and they became cases of established D.A.H. Other patients, again, having complained of no symptoms, were told they had heart trouble on examination by medical officers, and were put to bed or told to avoid any exertion. Such treatment often resulted in the patients discovering that they had tachycardia or slight breathlessness on exertion, or an occasional "missed beat" when lying in bed. The belief that serious heart mischief existed, having once been established, was very difficult to dispel, though not a few of these "manufactured" heart cases (especially those eligible for demobilisation) declared that they were sure there was nothing wrong with their hearts and were indignant at their transfer to a Heart Centre.

Goodhart says, "It is a bad day for a man when he first knows he has a heart," and this is especially true in the case of an irritable heart without structural changes. The importance of the correct assessment of symptoms arising during convalescence, and the proper management of that state, cannot be too strongly urged, in the light of the experience gained in dealing with the effort syndrome. It is exercise, judicially graduated, that is to prevent the development of D.A.H. after acute infections, and persistent treatment on the same lines to effect its cure in cases where it has been established, not rest and avoidance of all physical exertion.

One other point must be mentioned to complete these observations. Although the pursuit of physical exercise is generally regarded as a great characteristic of the people of this country, it is surprising to find what a great number of boys and men take practically no exercise. There is much too strong a tendency to excuse boys and girls from physical exercise and games because they are "weakly" or have "weak hearts," and there are far too many men who are content to watch a football match rather than play themselves or take exercise in some other form.

THE USE OF
AUTOGENOUS BONE GRAFTS
IN THE TREATMENT OF CERTAIN SIMPLE FRACTURES OF BONE.

BY BASIL HUGHES, D.S.O., M.A., M.B., B.C. CAMB., B.SC. LOND., F.R.C.S. ENG.,
ASSISTANT HONORARY SURGEON, CHILDREN'S HOSPITAL, BRADFORD; SURGICAL PATHOLOGIST, ROYAL INFIRMARY, BRADFORD.

THERE are to-day very few fractures of bone in which a satisfactory length and alignment cannot be obtained without resorting to open operation. The enormous preponderance of cases of bone fracture amongst the sum-total of wounds inflicted upon humanity during the past war has afforded great scope for originality in the introduction of newer methods of treatment and improved apparatus, which have sufficed to effect and maintain a satisfactory length and alignment not only in the case of simple fracture, but also in the most extensive type of compound and comminuted fracture. The popular war-splint, which was either Thomas's original knee-splint or some modification thereof, largely supplanted the pre-war wooden splints and plaster, and in so doing removed many objections to the latter apparatus in that the difficulty in maintaining length and alignment, the risk of compression and constriction and consequent delayed union occasioned thereby, ischæmic paralysis, and the like, were overcome.

There are still, however, a few simple fractures difficult to treat satisfactorily without open operation. These include fractures situated in the immediate neighbourhood of the hip- and shoulder-joints, which are often followed by osteo-arthritic changes unless a very accurate reduction is obtained, and spiral fracture of the lower third of the tibia where imperfect length and alignment will lead to faulty transmission of body-weight accompanied by its attendant evils. It must be remembered that every change in the formation and function of a bone is attended by certain and definite changes in its internal architecture (Wolff's law), hence a true length and alignment are of paramount importance.

Bone Grafts: their Fate, and Advantages over Plates and Screws.

In order that a bone graft may grow and function certain conditions are essential:—

(1) The graft must be autogenous. Bone transplanted from the lower animals to man or from one individual to another lives and functions only very exceptionally.

(2) The graft must be suitably nourished. A piece of bone transplanted from one part of the body to another will continue to live if strict asepsis has been observed; there is abundant evidence to prove that it can acquire the requisite nutrition from the lymph of the part in which it is lodged until such a time as its own blood-supply becomes established.

(3) When removing the graft it is advisable to include both periosteum and endosteum, for by such means earlier vascularisation and consequent union of the graft are undoubtedly obtained.

(4) When once the graft has commenced to unite a certain amount of movement of the muscles can with advantage be allowed. By this means the correct lines of stress and strain will become established in the graft according to Wolff's law.

There are several theories to explain what actually happens to the bone graft. The important question seems to be, is the graft osteogenetic or is it not? Some hold that all the bone in the graft is absorbed, and that the new bone is formed entirely from the periosteum. This view would gain support from the work of Stiles in his sub-periosteal resection of bone for tubercular disease, and from the work of Leriche on esquillectomy for war fractures. Macewan's view that the new bone is formed by proliferation of osteoblasts within the bone itself, and is independent of the periosteum, directly contradicts the above. It seems that a solution to the controversy rests in a real understanding of what is meant by the true periosteum. If the periosteum includes the true cambium of bone—that is, the layer including Sharpey's fibres—then without a doubt such a structure is osteogenetic. Another view is that the graft is not in any way osteogenetic, but simply acts as a scaffolding which in due course is absorbed and replaced by new bone by immigration into it first of osteoclasts and later of osteoblasts from the adjacent bone. My own experience leads me to believe that all these views are in part correct, if the periosteum be taken to include the true cambium of the bone, and in cutting the necessary grafts I have included periosteum, compact bone, and endosteum.

Early and repeated skiagrams of the grafts have shown partial rarefaction only about the periphery of the graft and not a complete rarefaction, whereas new bone formation can be seen to be taking place from the graft itself.

Although many brilliant results have been obtained through the fixation of fractures by means of plates and screws, it cannot be denied that the procedure involves the introduction into the tissues of a lasting foreign body, which cannot be removed by osteoclasts and replaced by new bone. Sooner or later rarefaction of the bone takes place around the screws and the plate works loose. Pain of a boring character may occur in the bone, and, worse still, a low form of suppuration may take place even as late as four years after the introduction of the plate. This is specially prone to occur if the patient's resistance be lowered by any debilitating disease such as malaria. I removed a piece of silver wire from a patient's patella owing to suppuration occurring two and a half years after its introduction; also a plate and screw from the femur of another patient four years after its introduction, for a similar reason. I have met with other cases in which removal of the foreign body has been necessary owing either to pain, suppuration, or the plate working loose. An examination of the pus in three cases showed *Staphylococcus aureus* to be present, but in two other cases no organisms could be found either in a stained film or by culture. Further, in my experience union of the fracture has never been so rapid or natural in the cases in which plates have been used as in those in which the bone graft has been employed. Moreover, in not a few cases the introduction of a plate has been followed by non-union of the fractured bone.

On the other hand, in using a bone graft we are not dealing with a foreign body, but with living tissue which in time becomes part of the bone and in which the lines of stress and strain eventually conform according to Wolff's law. The operation for bone-grafting is certainly more extensive and involves opening up the medullary cavity, but the latter is of no moment if strict asepsis be observed. The operation for bone-grafting takes a longer time than fixation by plates and screws; the technique is more exact and difficult and requires considerable practice. The type of graft called for in the case of simple fracture is almost invariably the "sliding graft."

Operation.

The very strictest asepsis is called for in this branch of surgery, for if once infection gains access there is not only the risk of osteo-myelitis with its sequelæ becoming established, but death of the graft will certainly follow. It is advisable to give two or three inoculations of staphylococcus aureus vaccine prior to the operation. It is to-day very advisable to ascertain whether or not the patient has had malaria, because malaria exerts a very baneful influence upon the bone marrow. If any malaria is present it should be treated without delay. Operations upon bone are not so satisfactory in malarial countries as they are at home, and simple fractures do not unite so readily in malarial subjects. Similarly, if the patient has at any time suffered from syphilis it should be ascertained that he is cured, as operations upon the bones of syphilitics at any period of the disease are apt to be disappointing. All skin infections, such as acne, boils, &c., should be corrected before operation, and a careful examination of the urine undertaken in order to exclude albuminuria and glycosuria.

After having thoroughly cleansed the skin of the part the limb is emptied of blood and a tourniquet applied. In case of fracture about the shoulder and hip-joints digital pressure, if possible, should be employed. An incision is now made down to the bone and the site of the fracture thoroughly exposed. The edges and sides of the wound are carefully protected with tetracloths and the bone ends are seized with forceps. While the necessary extension is made by an assistant the ends are accurately approximated and held in position with Lane's forceps by another assistant. The graft should be wedge-shaped and made to include periosteum, compact bone, and endosteum. It is then made to bridge the fracture, and is secured in its place by means of kangaroo tendon in the manner shown in the figure. Throughout the operation it is desirable to keep even the gloved finger out of the wound. Only boiled instruments should enter the wound, and all swabbing should be done by means of dry sterile swabs on the end of forceps. When the graft is satisfactorily fixed the soft parts should be allowed to cover it and the skin approximated with a continuous suture or Michel's clips. The limb is then put at rest on a splint, and the stitches can be removed on the tenth day.

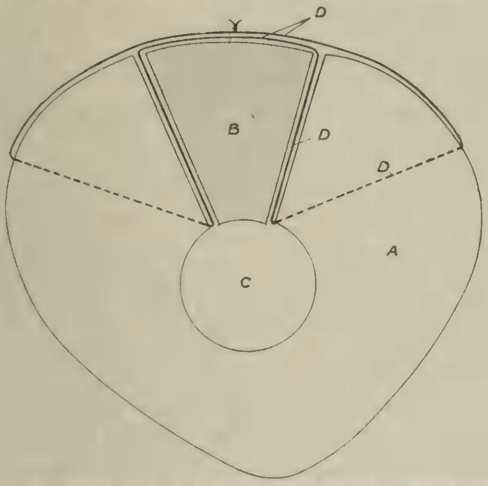

Diagram of cross-section of bone, showing how the wedge-shaped graft is made secure. A, Shaft of bone. B, Graft. C, Medullary canal. D, Kangaroo tendon.

At the end of the third week the patient may begin to use his toes or his fingers, and by these means the bone graft to some small and sufficient extent begins to function, and thereby the correct lines of stress and strain crystallise out according to Wolff's law.

Remarks.

The graft has usually grown in firmly by the end of the sixth week, and at the end of the eighth week the patient may begin to use the limb. Skiagrams taken after the tenth week show the graft to be almost indistinguishable both in texture and quality from the adjacent bone.

Of a particular series, including 15 cases, two were fractures of the surgical neck of the humerus and one a fracture in the upper third of the femur. One was a fracture of the neck of the femur; this case was treated by driving a bone peg, fashioned from the tibia, through the great trochanter into the head of the bone via the neck. One case was a fracture in the upper third of the shaft of the humerus, while the remainder were spiral fractures of the tibia in its lower third. One case suppurated despite the strictest aseptic precautions, but unfortunately this patient contracted severe malaria after the operation. Nevertheless, in this case the graft grew in and the patient did well under intensive treatment with quinine.

Grafts will grow and function in cases of mildly septic fracture, but I hope to deal with their uses in this connexion in a subsequent paper. I think that from every point of view the autogenous graft is superior to the plate and screws or to the use of any other kind of foreign body. The results have been so gratifying and excellent that I shall always employ it in future for those cases that call for open operation. In all of the above cases Albee's bone-grafting instruments were used.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

TORSION OF THE APPENDIX.

BY EDMUND C. BEVERS, M.B., B.CH. OXON.,
F.R.C.S. ENG. AND EDIN.,
HONORARY SURGEON, RADCLIFFE INFIRMARY, OXFORD.

TORSION of the appendix would appear to be a rather rare condition; the only previously recorded case that I have been able to find is that by Mr. J. E. Payne in the *British Journal of Surgery* for October, 1918. The following case, which came under my care in December, 1918, may therefore prove of some interest.

E. F., aged 35, was admitted to the Radcliffe Infirmary, Oxford, suffering from abdominal pain and vomiting; 60 hours before admission she was seized with severe pain in the right iliac fossa during the night and vomited almost at once. The pain increased in severity and vomiting continued at intervals. On admission her pulse was 120 and her temperature 100° F., the abdomen was slightly distended and generally rigid, this rigidity being most marked over the lower half of the right rectus, and there was acute tenderness on pressure in the right iliac fossa. I regarded the case as one of acute appendicitis with perforation, and operation was at once undertaken.

The abdomen was opened through a muscle-splitting incision, the peritoneum was injected and a little clear fluid escaped. The appendix was found hanging over the brim of the pelvis, both it and the meso-appendix were much swollen and dark purple in colour, and in places becoming black. At the base of the appendix and close to the cæcum were two complete twists, there were no adhesions, and the appendix was quite free in the peritoneal cavity. The appendix was removed and the abdomen closed without drainage, recovery being uneventful.

The appendix was 3 inches long, in a condition of acute gangrene, and contained a small concretion near the tip.

Remarks.

It is difficult to be certain of the sequence of events in this case. The torsion may have been primary and responsible for the gangrene; on the other hand, there is no particular reason why a cylindrical organ like the appendix should undergo torsion. It is much more probable that the distal end of the appendix became inflamed and swollen, and that the torsion followed later. An appendix with its distal end enlarged and swollen approaches closely the pedunculated type of organ in which torsion is common.

In view of the large number of appendix operations performed every year, and the wealth of literature on the subject, the meagre records that exist of torsion of the appendix suggest that this condition must be a rare one.

TOBACCO AMBLYOPIA IN A WOMAN.

BY MONTAGUE L. HINE, M.D. LOND., F.R.C.S. ENG.

IN order to put others on their guard when examining a case of toxic amblyopia in a woman, or one in which, in default of anything more definite, a diagnosis of retrobulbar neuritis might be made, I think the following case is worth reporting.

Mrs. M., aged 51, married, in April, 1919, consulted me as she could not see anything clearly. Fifteen months previously her sight had been affected, but after taking some medicine from her own doctor it improved somewhat. Some four months before seeing me the sight had again failed, so that she was quite unable to read. Her medical attendant could find nothing wrong with the eyes, and glasses were of no benefit. Ultimately she was sent to consult me.

Vision was reduced to 6/60 in each eye, and there was a very large central colour scotoma for red and green, and an incomplete central scotoma for blue. The fundus showed no changes save slight pallor of the optic discs. She admitted smoking cigarettes, but at first said they were "chiefly Grey's, and so forth," and it was only when she was about to leave, after I had exhausted every form of toxin I could think of, that she made the unusual admission that she was "very fond of shag cigarettes," which she got her husband to make for her, when he was smoking his pipe. Prohibition of all smoking soon accomplished a cure, though she did not revisit her medical attendant as I advised.

The smoking of "shag" cigarettes as a cause of amblyopia in a private patient is not one that would be frequently suspected, but in these days, when smoking amongst women is so much on the increase, and there are plenty of patients about whose ability to pay fees is no indication of their previous social status, it is well to bear this case in mind.

Weymouth-street, W.

A CASE OF JUVENILE TABES.

BY DAVID KERR, M.B., CH.B. EDIN.

IN the case here described I suggest that the "painful" hip must be interpreted as lightning pains, and that the three striking features of the case—(1) lightning pains, (2) primary optic atrophy, (3) absent knee-jerks—establish the diagnosis of juvenile tabes in spite of the absence of a history pointing to hereditary syphilis and of the negative Wassermann reaction of his blood and cerebro-spinal fluid.

J. E. G., a boy, aged 14 years, was admitted to the St. James's Infirmary, Balham, on May 8th, 1919, suffering from painful hip of one month's duration. The family history was not in any way noteworthy; a cousin of the patient had had some eye trouble, probably interstitial keratitis. There was no eye trouble in any other relation, and syphilis in the patient's immediate relatives was strongly denied. The pain occurred suddenly, and was of such intensity as to make him cry out; it seldom lasted more than an hour, and then suddenly ceased, leaving him placid and comfortable. He referred the pain to his back, hip, or left side, and as passing from the left flank towards the groin. Except during the actual time of the attack he was able to run about and slept well. The pain could not be localised in any joint. X ray and repeated urine examinations ruled out other possibilities.

In July failing vision was noted—diminished visual acuity, marked contraction of field, abolition of colour fields. Ophthalmoscopic examination showed a somewhat pale disc, a slight total excavation, indications of lamina cribrosa not evident; there was a well-marked chorioidal pigment ring. Vision steadily deteriorated, and soon complete blindness ensued.

On Nov. 8th an attack of vomiting occurred. He wasted a little in the first three months; later his nutrition was well sustained. On only two occasions did he complain of headache. Knee-jerks absent. No paralysis. No impairment of sensation. The boy is bright and intelligent.

The vomiting may have been a gastric crisis; no other cause could be found.

I am indebted to Dr. W. L. Maccormac, medical superintendent of the St. James's Infirmary, for permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

REMOTE EFFECTS OF THE SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCERS.

A MEETING of this section of the Royal Society of Medicine was held on March 3rd, Sir JOHN BLAND-SUTTON, the President, being in the chair.

Mr. H. J. PATERSON read a paper on the Remote Effects of the Surgical Treatment of Gastric and Duodenal Ulcers. He considered these results from three points of view: (1) clinical, or the result of the operation as regards the patient; (2) physiological, or the result of the operation as regards the secretions of the stomach and the metabolism of the body; (3) pathological, or the influence of operation on the healing of the ulcer and the complications which might ensue from surgical treatment.

1. *Clinical.*—The conclusions were based on his first 450 cases, all performed over seven years ago. An analysis of this series gave the following results: 51 of the patients had died of other diseases, having lived for more than two years after the operation without any recurrence of their gastric disorder, and 270 were alive and quite well. The number of those who were dead might seem large, he said, but the series dated from 20 years ago, and one patient operated on in 1901 was now 81 years of age. Adding these two classes together gave a percentage of 80 per cent. who might be regarded as cured by the operation. In 9 per cent. the result might be classified as fairly good, the patients being relieved of their pain, but either suffering from occasional attacks of indigestion or having to exercise care in their diet. In 7 per cent. of the cases the operation might be classified as bad, in 4 cases a jejunal ulcer occurred, in 1 there was a recurrence of a duodenal ulcer, and 23 cases were complete failures, probably due in some cases to leaving in the abdomen a diseased appendix in the days before the rôle of the appendix in producing gastric symptoms was appreciated. There must be a definite pathological indication for the operation, and some of the failures were due to disregard of this vital rule. An operation performed on a clinical diagnosis unconfirmed by pathological findings was a mistake both in diagnosis and in operation.

2. *Physiological.*—A study of the physiological effects of gastro-jejunostomy was important, as it showed how gastro-jejunostomy acted and taught the proper indications for its use. There were two striking and constant effects of gastro-jejunostomy on the stomach contents: (1) the diminution of the total acidity; and (2) the increase of mineral chlorides. Tables of gastric analyses were shown illustrating this and showing the amount of free hydrochloric acid and mineral chlorides before and after the operation. The diminution of the total acidity was due partly to the diminution of the total chlorides secreted by the gastric mucosa and partly to the neutralisation of free hydrochloric acid by the small quantity of bile and pancreatic juice which flowed back into the stomach through the anastomosis. The increase of mineral chlorides was constant and permanent. It was not the result of increased activity of the gastric mucous membrane, and must therefore be due to chlorides added from without. The inference, therefore, was irresistible that the increase was due to the mineral chlorides of the bile and pancreatic juice which gained entrance to the stomach through the anastomosis. This was borne out by the fact that if the gastro-jejunostomy were undone there was a decrease towards the normal after restoration of the alimentary canal to its normal condition. Tables of analyses were also shown to illustrate this. Other tables showed that when an entero-anastomosis had been performed in addition to the gastro-jejunostomy, and the bile and pancreatic juice diverted through this opening, no increase of mineral chlorides was present. The difference in the average increase of mineral

chlorides after the different types of gastro-jejunostomy was so small as to be negligible, so that physiologically the type of operation performed was unimportant, with the exception that all types of Y operations and gastro-jejunostomy with entero-anastomosis were unsound. The conclusion to be drawn was that gastro-jejunostomy was not a mechanical but a physiological operation, and its action was to enable nature to counteract hyperacidity and neutralise the effects of hypersecretion. With regard to the effect of the operation on metabolism, a series of experiments showed that the operation did not appreciably diminish the proportion of nitrogen or fat absorbed from the food. We were, therefore, justified in concluding, by both clinical and pathological evidence, that the operation of gastro-jejunostomy did not appreciably interfere with the metabolism of the human body, and was compatible with the enjoyment of perfect health.

3. *Pathological.*—Post-mortem examination in five instances, made four or five years after an anterior gastro-jejunostomy with a long loop, showed that the anterior surface of the stomach had been drawn downwards and posteriorly, while the afferent limb appeared to become shortened, measuring 4 to 5 inches instead of 10 to 12 inches. Post-mortem examination on 16 occasions showed that in all of the cases the ulcer, whether gastric or duodenal, had healed and the anastomotic opening had diminished from 2¼ to 2½ inches to 1¾ to 2 inches in length.

Jejunal Ulcer.

Jejunal ulcer was, perhaps, the most serious after-complication of gastro-jejunostomy. For ulcers situated around the site of the anastomosis he suggested the description "gastro-jejunal ulcers," for those situated in the jejunum he would retain the name "jejunal ulcers." From the records available he thought that we were justified in assuming that the proportion of cases in which jejunal or gastro-jejunal ulcers followed gastro-jejunostomy was between 1 and 2 per cent. There were strong grounds for believing that jejunal ulcer was the result of the toxic action of free hydrochloric acid on the jejunal mucous membrane, the hydrochloric acid so injuring or killing the cells of the jejunal mucous membrane that they were readily digested by the intestinal juice. Jejunal ulcer was usually associated with hyperacidity of the gastric contents, and in the majority of instances the ulcer was situated either opposite the anastomosis or just below it in the efferent limb—that is, just where the acidity of the gastric contents, when they reached the jejunum, was greatest. Usually, after gastro-jejunostomy, the small amount of bile and pancreatic juice which flowed back into the stomach was sufficient to neutralise or reduce to normal the free hydrochloric acid present in the gastric contents; but, if the amount of free hydrochloric acid in the gastric contents was excessive, the bile and pancreatic juice might not neutralise the free hydrochloric acid sufficiently to prevent its toxic action on the jejunal mucous membrane, when it came into contact with it. From observations which he had made on a patient in whom a jejunal ulcer had perforated through the abdominal wall, it was seen that the gastric contents showed a high degree of acidity, which was not neutralised by the bile and pancreatic juice, as was shown by analysis of the fluid escaping from the fistula. After a week on a purely milk diet, the free hydrochloric acid in the gastric contents was reduced to about normal, so that the fluid flowing from the fistula contained only 0·004 per cent. As its percentage in the gastric contents diminished rapidly on a milk diet, the excess was probably due to errors in diet. Jejunal ulcer was sometimes attributed to damage to the intestine, caused by the use of clamps. There were two objections to this hypothesis: (1) the interval between the operation and the onset of symptoms of jejunal ulcer varied in his cases between two and five years; (2) the ulcer usually occurred in a situation not gripped by the clamps. In a few cases jejunal ulcers were probably infective in origin. In such cases the ulcer occurred within a very short period after the gastro-jejunostomy, and the ulcers were usually multiple.

The conditions under which jejunal ulcers might arise might be summed up as follows: 1. Hyperacidity of the gastric contents, so that the bile and pancreatic juice were unable to neutralise completely all the acid entering the jejunum. 2. Normal percentage of hydrochloric acid in the gastric juice, but excessive secretion, so that the amount of hydrochloric acid discharged into the jejunum was greater than could be neutralised, and there was a continual action on the jejunal mucous membrane of a weak solution. 3. Diversion of the course of the bile and pancreatic juice, so that part of the jejunum was exposed to the action of the gastric contents unmixed with bile and pancreatic juice, as after operations of the Y type, and gastro-enterostomy with entero-anastomosis. 4. Normal acidity and amount of gastric secretion, but incomplete neutralisation in the jejunum owing to temporary diminution of the flow of bile and of the secretion of pancreatic juice.

Dr. Charles Bolton, in a series of experiments, found that feeding guinea-pigs on a solution of hydrochloric acid up to 0·7 per cent. produced no effect whatever, but a solution above that strength produced gastric lesions identical in character with those produced by a gastrotoxic action. He concluded that the gastric juice was not only concerned in the initiation of a gastric ulcer, but also in its tendency to spread and to become chronic; and that the gastric juice owed its destructive power primarily to the hydrochloric acid contained in it, and the damage done to the wall of the stomach varied in proportion to the strength of the acid present. These conclusions, Mr. Paterson thought, might be applied with even greater force to the action of hydrochloric acid on the jejunal mucous membrane, which, under normal conditions, was unused to the presence of the acid gastric contents.

Gastro-jejunal Ulcer.

Much of what had been said applied, he continued, to this variety of ulcer. Hyperacidity was an important factor in both, with this difference that jejunal ulcers were the result of altered physiological conditions produced by the operation, whilst gastro-jejunal ulcers were probably a direct consequence of operation. If the mucous membrane were roughly handled or injured, or unduly constricted by too tight a suture, or if coaptation of the gastric and jejunal mucous membranes were imperfect, ulceration would follow at the line of the suture. If hyperacidity or hypersecretion existed, then the ulcer, instead of healing, might persist or spread, and eventually give rise to symptoms, and might lead to great constriction or even closure of the anastomotic opening. That the use of a non-absorbable suture was a cause of gastro-jejunal ulcer he regarded as non-proven.

If his views were correct the practical point arose as to what were the causes of hyperacidity after gastro-jejunostomy. We must draw a clear distinction between two classes of cases: (1) those in which hyperacidity was present before and persisted after the operation, and (2) those in which, after a period of normal or subnormal acidity following operation, the gastric contents subsequently became hyperacid. Hyperacidity persisted after the operation for one of two reasons: (*a*) extreme hyperacidity before operation, so that the bile and pancreatic juices were unable to reduce the acidity of the gastric contents to normal unless the patient was kept on a milk diet for some months; or (*b*) an opening which was too small or inefficient. If the opening were too small hypersecretion might persist, and any kink or twist at the site of the anastomosis would prolong the contact of the gastric contents with the jejunal mucosa. Hyperacidity of the gastric contents succeeding a period of normal or subnormal acidity was probably due to too small an opening or to indiscretions in diet. Operation was only an incident in the treatment of gastric and duodenal ulcers, and too much emphasis could not be laid on the importance of a carefully regulated diet after operation. In most cases indiscretions in diet played the chief part in causing post-operative hyperacidity, and so predisposing to the occurrence of gastro-jejunal and jejunal ulcers. A prolonged period of restricted diet was imperative, especially in cases in which there was hyperacidity before operation. In all cases of hyperacidity increase in diet should be controlled by gastric analyses at regular intervals. Every case of recrudescent pain of a constant character after gastro-jejunostomy, especially when associated with hypersecretion, should be regarded as a case of potential ulcer and treated accordingly.

The Effect of Gastro-jejunostomy on Ulcers of the Lesser Curvature.

In the course of the discussion which followed,

Mr. GARNETT WRIGHT spoke of the effects of gastro-jejunostomy on lesser curvature ulcers and of secondary ulceration. Though in a number of cases this operation would effect a cure, yet there were many patients in whom temporary relief was followed by a disappointing return of symptoms, and subsequent operation showed the presence of an unhealed ulcer. He now adopted one or other method of excision: either wedge-shaped excision and gastro-enterostomy or partial gastrectomy, the last method being the one he preferred. It had the advantage of removing the ulcer-bearing area, as was pointed out by Rodman in 1904. The largest statistics (Mayo Clinic) gave the mortality as 7 per cent. The operation which he did at present was the anterior Polya operation.

Secondary ulceration was the most important of the harmful remote sequelæ of the operation of gastro-jejunostomy. It was almost impossible to get the data for a reliable estimate of its frequency. In its slighter manifestations it was a much commoner condition than was usually suspected, and in many patients in whom a recurrence of the original ulceration was suspected the real lesion was a new ulceration in the anastomosis or in the jejunum. In considering the causation of such secondary ulceration three factors must be taken into account: (1) the digestive action of the gastric juice; (2) sepsis; (3) trauma. A combination of two or more of these factors was necessary to the production of secondary ulceration.

(1) The influence of gastric digestion was shown in the distribution of the ulcers in a position subject to the action of the non-neutralised gastric juice and in the greater liability to ulceration in operations complicated by some form of entero-anastomosis. There was a steadily diminishing power of resistance to gastric digestion as one descended the small intestine. No secondary ulcers had been reported after gastro-duodenostomy, and more occurred after anterior than after posterior gastro-jejunostomy.

(2) Sepsis. Excluding the gross sepsis which might possibly be introduced at the time of operation, there was a potent source of infection in the presence of an unhealed gastric or duodenal ulcer. Streptococci were constantly present in such ulcers, and streptococci had been recovered in large numbers from gastric and duodenal ulcers from patients on whom he had operated, very few colonies being recovered from the rest of the mucosa. An anastomosis established with an unhealed ulcer in existence in the stomach or duodenum was exposed to the risk of infection from the ulcer, and he thought that a certain number of secondary ulcerations, especially of the gastro-jejunal type, could be explained in this way.

(3) Trauma was often an accessory agent in the production of secondary ulceration, and this might be due to the technique of the preliminary operation. In 14 out of 155 cases Murphy's button or some form of bobbin had been used. In 13 a continuous non-absorbable suture was considered to be the exciting cause of the ulceration, but cases had occurred when only absorbable suture material had been used. The bruising of the bowel or stomach produced by the use of heavy clamps had been blamed, and Hartman considered this a very important factor. The more recent cases seemed to be of the gastro-jejunal type, and he wondered whether the through-and-through hæmostatic stitch did not lead to a stoma in the mucosa in which the mucosa was adherent in a thin line all round. Such a stoma would be more liable to injury by pieces of food than one where the mucosa was freely movable over the deeper parts. But the cause of the original ulceration was still probably active, and where this was so patients would develop fresh ulcers in spite of all efforts.

Morbid anatomy of secondary ulceration.—With regard to this he said that the number of cases of jejunal ulceration slightly exceeded the gastro-jejunal variety; out of 142 cases, gastro-jejunal occurred in 63, jejunal in 79. Of the jejunal, in 54 the ulcer was on the efferent loop, in 2 on the afferent loop, and in 10 opposite the stoma—i.e., on the mesenteric border of the jejunum. In 9 cases the ulcers were multiple and in 4 the site was not definitely stated. Acute perforation into the peritoneal cavity took place in 31 cases, and was more liable to happen after anterior gastro-enterostomy (28 per cent. of the cases as against 15 per cent.). Chronic perforation into the abdominal wall was often seen after anterior gastro-enterostomy, large inflammatory tumours and sometimes external fistulæ being produced. After the posterior operation chronic perforation into the mesentery was frequent, the mesentery of the colon becoming thickened and contracted, until finally the colon was brought into contact with the ulcer, perforation into the colon and jejunocolic fistula resulting. Fistula into the colon was almost invariably secondary to a posterior gastro-enterostomy. It occurred in 21 out of 142 cases which he collected, and in only two instances was the preliminary operation an anterior one, and in one of those it was of the retro-colic variety. In the case of ulcers opposite the stoma—i.e., in the mesenteric border of the jejunum—the contraction of the ulcer tended to produce a spur at the gastro-enterostomy opening and consequent obstruction. Heavy clamps might cause such ulcers, as they were situated where the pressure of clamps was likely to be exerted.

Specimens to Show Successful Results of Operation.

Mr. JAMES SHERREN said that if the appropriate procedure was adopted the ulcer healed permanently, and any symptoms which might arise later were the outcome of ulcerative or mechanical changes associated with the anastomosis. Chronic ulcers of the stomach and duodenum healed as the result of gastro-jejunostomy correctly performed unless chronic perforation had occurred, the floor of the ulcer being formed of liver or pancreas, thus preventing the contraction necessary to sound healing. In his experience recurrence of a simple ulcer after suitable surgical treatment was unknown. He had not seen it at post-mortem examinations nor at second operations carried out for other conditions. The only instance in which he had seen the ulcer unhealed had been at second operations for posterior eroding ulcer treated by gastro-jejunostomy alone, and these he now invariably dealt with by partial gastrectomy. A specimen was exhibited showing healing of a chronic duodenal ulcer more than 11 years after gastro-jejunostomy, the patient having died of primary carcinoma of the liver as seen on post-mortem examination. Two other specimens showed the ulcers healed 8 and 3 years after operation.

He believed that the action of the gastro-jejunostomy was twofold—it reduced gastric acidity and led to a more rapid emptying of the stomach. Its good effects were not solely or mainly mechanical. Malignant disease of the stomach might occur at remote periods after treatment of chronic gastric ulcer by gastro-jejunostomy alone. It was the probable cause of death in three of his series at 7, 5, and 4 years after operation. As no post-mortem examination was possible he was unable to say if it arose at the seat of the simple ulcer. They were all cases which he would now treat by partial gastrectomy. In 3 per cent. of chronic ulcers of the stomach which he had removed at operation, the naked-eye diagnosis being simple and there being no evidence or suspicion of malignancy, carcinoma starting at one edge was discovered on microscopic examination. He knew of no case of carcinoma of duodenum arising after operation for chronic duodenal ulcer, but in 2 cases in which the ulcer was involving the stomach further operation became necessary within 18 months, and revealed carcinoma of the stomach, the duodenal ulcer being healed.

Post-operative vomiting of the regurgitant type was due to errors of judgment or technique. In all his cases except the first some abnormality was present at the first operation and some definite mechanical change was found at the second. Gastro-jejunal or anastomosis ulceration was due to the use of unabsorbable suture material for the inner or outer layer, and was the only cause of stricture. He believed that an anastomosis ulcer might become malignant. Jejunal ulcer was due to failure of the operation sufficiently to lower gastric acidity at the same time that it failed to remove the cause of the original ulcer or damaged the jejunum. It was almost unknown after gastro-jejunostomy for chronic gastric ulcer. In all cases of true jejunal ulcer gastric acidity was higher than it should be when compared with the pre-operative, unless the ulcer was communicating with the colon, when a low acidity was the rule. The use of the jejunal clamp was one of the causes of jejunal ulcer, but this of itself would not be enough unless the acidity remained high. He had noted bruising by clamp in 6 cases in which he had records of test meals both before and after operation. In 3 gastric acidity remained high and ulcer developed in all; in the others the acidity was markedly lowered, and there had been no symptoms pointing to ulceration. The operation had been performed over two years previously.

Two specimens were exhibited bearing on the question of jejunal ulcer. One showed the result at a late period after operation. A jejunal ulcer developed as a purely local complication and was excised. The gastro-jejunostomy opening and the jejunum were normal. The other showed a sequel which he had found in over a third of the cases of true jejunal ulcer—perforation into the colon. The ulcer, which had perforated into the colon, was seen free of the anastomosis, which was healthy and showed no sign of scarring. Out of 389 cases of chronic duodenal ulcer which he had operated upon over a period of two years he had been able to keep 348 under observation. Of these, 318 had remained quite well, and might be claimed as successes. This was over 90 per cent. of those traced, or 80 per cent. of those operated on. He had had to re-operate on 19 for secondary ulceration, 10 being jejunal. Of the remainder, all except one, who had, he thought, an anastomosis ulcer, expressed themselves as better for the operation. Of 310 cases of chronic gastric ulcer operated on during the same period, over 80 per cent. of those kept under observation were successful, or 75 per cent. of those operated upon; 14 had second operations, 5 for recurrence after excision alone, 5 for excision of posterior adherent ulcers that had not completely healed after gastro-jejunostomy alone. All these became successes, but were not included. Four were operated on for secondary ulcers, only 1 of which was jejunal. In the remainder complaints were few, and all expressed themselves as better for the operation. The remote result in the treatment of chronic gastric ulcer improved as individual experience ripened.

Failures Due to Injudicious Selection of Cases.

Dr. ROBERT HUTCHISON said that he was a whole-hearted believer in the surgical treatment of chronic gastric and duodenal ulcer, but one must not expect too much. He would not himself regard the operation as even comparatively unsuccessful merely because the patient had occasional indigestion afterwards. It must be remembered that gastro-enterostomy did not make a patient immune to functional indigestion or to attacks of gastritis. He had seen, of course, a good many failures, and a disproportionate number of these seemed to come from certain districts. The bad results were perhaps more often due to injudicious selection of cases than to errors of technique, so perhaps the physicians were to blame for them more than the surgeons. Apart from gross mistakes in diagnosis, and the overlooking of other pathological conditions in the abdomen such as chronic appendicitis or gall-stones, it seemed as if the co-existence of gastroptosis or marked gastric atony militated against a very successful result. In gastroptosis this might be due to the greater curvature sagging down, so that the anastomosis came to be too high up, or a pouch formed behind it in which stagnation of contents took place. He had never seen recurrence of a duodenal ulcer after the operation, and in recent years anastomosis ulcer seemed to be commoner than jejunal ulcer. He accepted Mr. Paterson's explanation of the production of the latter as being due to a continued hyperacidity of the gastric contents, but could not agree that this was the result of errors of diet. In so far as it was not due to the anastomosis opening being too small, it was to be regarded, he thought, as a functional disorder of the stomach, the result of nervous disturbance. In order to prevent its occurrence the state of the patient's nervous system had to be considered, and at the same time alkalies should be given in all cases in which the gastric acidity was excessive. He preferred to use the earthy carbonates for this purpose rather than bicarbonate of soda. He would like to have an expression of surgical opinion as to the relative advantages and disadvantages of occluding the pylorus at the time of the operation and its effect, if any, in preventing or promoting remote ill-effects.

Diagnosis.

Dr. C. BOLTON said that since 1919, when he had reported on 27 cases of jejuno-colic fistula, he had had during the past four years 4 other cases. Of these 3 had recovered after operation by Mr. Wilfred Trotter, and in the other case the fistula had been found post mortem. All the 31 cases had occurred in the male sex, usually from 30 to 50 years of age. The time after the performance of the gastro-jejunostomy at which the fistula had appeared varied from a few weeks to 10 years. He spoke principally about the diagnosis, first considering the exact conditions present. The cause of the fistula was the perforation of a gastro-jejunal or a jejunal ulcer into the transverse colon, such an ulcer resulting from the operation of gastro-jejunostomy. The position of the fistula depended upon the position of the ulcer. Usually the colon communicated indirectly with the stomach through the jejunum. The fistulous opening was situated within an inch of the stoma and to the left, the colon lying in front. Occasionally the colon communicated directly with the stomach if the ulcer was of the gastro-jejunal type. It might also communicate both ways. If the colon communicated directly with the stomach the case was of no great medical interest, because the diagnosis was clear from the typical clinical spectacle of fæcal vomiting and eructations of foul gas, passage of undigested food in the motions, and wasting. If, however, the communication was indirect the condition was of great medical interest, for the diagnosis might be extremely difficult. As the stomach emptied, food passed down the efferent limb of the jejunum, only a small amount or none passing into the transverse colon. Leakage from the colon to the jejunum was more marked and more constant, as the colon continually contained liquid fæces, diarrhœa being a constant feature. The amount leaking into the jejunum depended upon the liquidity of the contents of the colon, the patient being much relieved when he was constipated. Besides, the fæces leaking into the jejunum passed more easily down into the small intestine than back into the stomach. The small intestine thus became infected, and this condition kept up the diarrhœa.

The diagnosis turned on the finding of fæcal material in the stomach contents. Vomiting might be only occasional and fæcal material was not constantly in the stomach, so that the physician might never obtain a view of the fæcal vomit. Vomiting might be absent and fæcal material only obtained by tubage of the stomach. Similarly diarrhœa, which was the earliest and most constant symptom, was liable to mislead the physician. The stools were loose, brownish-white in colour, and not very watery. There was no separate blood nor mucus. They did not occur particularly after a meal, but at any time during the day or night, when they were liable to keep the patient awake. The frequency varied from 3 or 4 to 12 in the day. There was commonly no undigested food present. Ferments were usually absent and the total fat was about normal. There were usually intervals when the motions were formed; the vomiting then stopped and the patient felt much better. Eructations of foul gas were present, but the patient usually brought up no more than occurred in simple indigestion. Intestinal pain was present and referable to both small and large intestines, but was particularly liable to be marked on the right side, where it was of a griping character. When this pain was associated with visible peristalsis a mistaken diagnosis of intestinal obstruction might be made, but the patient was always better when he was constipated and worse when suffering from diarrhœa. The peristalsis was due to narrowing of the colon in the region of the fistula. Wasting was constantly present. The appetite was not necessarily affected, and might be good or even excessive. X ray examination might show an opaque meal passing from the stomach into the colon, or the stomach might be seen to fill from the colon after an opaque enema. Other methods in use were the finding of easily recognisable substances in the fæces shortly after ingestion, the recovery of a coloured enema by tubage of the stomach, and the passage of air into the stomach after insufflation of the rectum or vice versa. The immediate prognosis after operation on these fistulæ was good. Of the 31 cases, 4 had had no operation, and all died—1 from perforation of the ulcer, another from hæmorrhage, and the other 2 from inanition. Twenty-seven were operated upon, and of these 21 recovered. Of the 6 deaths, 2 followed simple exploration of the abdomen, the fistula not being touched.

The Results of Short-circuiting.

Sir D'Arcy Power thought that short-circuiting for dilated stomach, the result of duodenal ulceration, was rarely followed by any untoward results. He described a case in which the patient had suffered from numerous attacks of abdominal pain. In 1903 he had lost 2 st. in weight, and presented the typical symptoms of pyloric obstruction. A posterior gastro-enterostomy was performed. He regained his normal weight, was able to resume full work, and was able to eat a City dinner without subsequent discomfort. He died in 1913 at the age of 58 from acute retention of urine due to an enlarged prostate. Post-mortem examination showed the stomach to be dilated and slightly hypertrophied. The opening between the stomach and jejunum was large and patent, and the mucous membrane of the stomach and small intestine appeared healthy. Microscopic examination of a section taken at the point of suture showed a sharp line of demarcation between the mucosa of the stomach and intestine. The results shown in the specimen were, he thought, those which followed normally in similar cases. The opening remains of the size it was made, the stomach does not entirely recover its normal size, but the patient is able to resume an active life. From time to time he becomes constipated, or he eats what he knows will give him indigestion. He then suffers from abdominal discomfort, becomes depressed, and believes that his former condition is returning. Gentian and rhubarb and a little advice as to dietetics soon cure him. It might be quite otherwise when gastro-enterostomy had been done for an actively bleeding duodenal ulcer. In many cases the patient is relieved by the operation, but he had had two or three in which the bleeding recurred, and in one case the hæmorrhage was so repeated and severe that the patient died some months after he had operated upon him. In cancer of the stomach and pylorus the operation was palliative, and—in hospital cases at any rate—did not appear to prolong life, though the pain and sickness were relieved. He did not advocate it, therefore, except when these symptoms were prominent, although it was surprising how well the operation was borne, even by patients who were greatly emaciated. So far as he knew, none of his patients had suffered from symptoms of "peptic ulcer," and for this he could assign no reason. He operated rather quickly, did not use intestinal clamps, sutured with No. 2 silk, and had shortened the jejunal loop from 9 inches in 1903 to 3 inches in 1920; otherwise his technique remained unchanged.

Mr. R. H. Jocelyn Swan wished to draw attention to the fact that there should be no pathological results from a gastro-enterostomy if performed for a definite mechanical lesion such as pyloric stenosis or prepyloric ulcer. He used very fine thread for all three layers, and after the anastomosis hitched up the distal 1½ inches of the jejunum to the transverse mesocolon in order to avoid any kinking of the new junction. He showed a specimen of carcinoma of the whole pyloric end of the stomach, which was commencing to involve the gastro-enterostomy opening made nine years previously for a cicatricial pyloric stenosis from old ulceration. Apart from this case, and one in which he had had to reopen in order to secure a spurting vessel at the jejunal side of the anastomosis, he had seen no case of jejunal ulcer follow a large number of anastomoses, and in several cases in which it had been necessary to reopen the abdomen subsequently for other conditions the opening had been fully patent.

Difficulties of Operation and Failures in Technique.

Mr. A. J. Walton's remarks were based almost entirely on his own personal experience. The total number of operations was 335, of which 321 were personally treated from the beginning. Of these 321 cases 10 required further operations, 3 for the onset of carcinoma, 3 for recurrent ulcers, and 4 for gastro-jejunal ulcers; in other words, 3·2 per cent. required further operative treatment. Few cases had been lost sight of, so that it was probable that this percentage was fairly correct. The remaining 14 cases had had their first operation performed by some other surgeon, and therefore it was impossible to estimate what percentage of recurrence they represented. The after-history showed that about 80 per cent. were complete recoveries.

The post-operative difficulties might be classified as follows:—

(*a*) The operation is unjustifiably performed. Gastro-enterostomy was sometimes performed without any clear evidence of the presence of gastric or duodenal disease; he wished especially to lay stress upon visceroptosis. Symptoms of this condition might simulate those of a gastric ulcer closely, and at operation local areas of spasm might be seen which appeared to be mistaken for chronic ulcers. Gastro-enterostomy would not only give no relief, but would often be followed by an aggravation of the symptoms. The one exception to this statement was an acute ulcer giving rise to severe hæmorrhage, which might be found with visceroptosis in young women. Under such circumstances a gastro-enterostomy might be of great value, but in his experience only when combined with pyloric occlusion.

(*b*) Gross lack of anatomical knowledge at the first operation. This he had found on three occasions. In two cases a junction had been made with the colon instead of with the jejunum; in the third case an anastomosis had been performed with the ileum 12 inches from the ileocæcal valve. In all three cases the opening had been so badly made that it was too small to function, and the patients might be said to have survived because there were two errors instead of one. Their symptoms were simply those of persistence of the ulcer.

(*c*) Some obstruction of the afferent and efferent loops, a condition now but rarely seen. Four different varieties of the obstruction might be recognised:—

(1) Too long a loop. With a long afferent loop there would be a tendency for the intestine to drag upon the stomach at the junction, so that the afferent and efferent loops became parallel, and a sharp bend with kinking was formed. This was especially likely to happen with an anterior gastro-enterostomy if the ante-colic method were used. Sherren's retro-colic method would overcome this when it was necessary to perform any anterior gastro-enterostomy. (2) Too short a junction. If too small an opening were made the attachment would become so narrow that a kink would occur somewhat similar to that in the last group of cases, the afferent and efferent loops becoming approximated so that the passage would not be clear. (3) Constriction by the opening of the mesocolon. It had always been advocated that the mesocolon be sutured to the junction, in the belief that if this step were not carried out a hernia of the small intestine might take place through the opening. This complication was a rare one, but if the suturing were not performed there was a much more common complication; the ring of the mesocolon would slip downwards and would approximate the afferent and efferent loops so that they would come to lie parallel and would thus be kinked. In fat patients, even if the mesocolon be sutured to the junction, the lower leaf of the meso-

colon might constrict and, owing to the thickness of this structure, the constriction might lie well below the junction and thus approximate the loops. Mayo advocated that in stout patients the mesocolon should be sutured to the posterior wall of the stomach some distance from the junction. (4) Axial rotation. If the jejunum were rotated upon its long axis, while the junction was being made, symptoms of obstruction would develop almost at once.

(*d*) The opening badly planned. It was well realised that such devices as Murphy's button were often left in situ; that they left too narrow an opening; that they often caused hæmorrhage; that they were followed by ulceration and constriction; and that their insertion could not be carried out more quickly than the safe method of an anastomosis by suturing. The faults which were more likely to be found to-day in the formation of the opening were: (1) The opening too small. To allow for constriction in the healing the opening should be at least 3 to 3½ inches long when the intestine was held between the clamps—that is to say, its circumference should be 6 to 7 inches. (2) The opening too high. However the opening be placed, whether it be vertical, retro-peristaltic, or iso-peristaltic, the lower portion of the opening should reach nearly to the greater curvature. (3) The posterior wall united to the anterior wall. He had always been struck with the ease with which it would be possible to pick up the posterior wall in suturing the two anterior layers and had always taken care to avoid this pitfall. He had seen the condition in one case in which the symptoms returned 18 months after an operation by another surgeon. (4) The opening wrongly placed in regard to the constriction. The commonest fault was that an hour-glass stomach was overlooked when associated with pyloric obstruction, and a junction was made between the jejunum and the distal pouch, thus failing to overcome the obstruction in the middle of the stomach. The reverse of this might sometimes happen with a double constriction, an opening being made into the proximal pouch alone.

(*e*) Gastro-jejunal and jejunal ulcers arise. (1) Gastro-jejunal ulcer. His own experience supported the view that this form of ulceration was due to the presence of a piece of silk suture. In the three cases of his series in which this occurred he had used silk sutures for the outer layer and had been able to find the suture at the second operation. A similar suture had been found in three out of the four cases where the operation had been performed by other surgeons. Since he had been wholly using catgut he had not had an example of the condition. That the increase of acid was also a factor was shown by the fact that in all of his cases the original operation was for a pyloric ulcer, in which condition the free hydrochloric acid was much higher than with a lesser curve ulcer. The ulcers all commenced either anteriorly or at one extremity and they tended to become adherent and to perforate into the colon. He thought that their method of production was as follows: As the first layer of through-and-through catgut suture was approaching its termination the mucosa was hidden from view and slipped out of sight so that the through-and-through suture picked up only the muscular and peritoneal coats. When the silk embedding suture passed over this surface it would not be covered by mucosa and a raw surface would be left, in the base of which was an unabsorbable foreign material, and under the influence of excess of acid this gave rise to a chronic ulcer. Such an ulcer might be prevented by taking special care to include the last piece of mucosa in the through-and-through suture and to use a catgut suture for the embedding layer. (2) Jejunal ulcer. In his own series he had not yet met with a true jejunal ulcer, and many of the specimens he had seen described as jejunal ulcers were continuous with the gastro-jejunal junction. He thought, therefore, that the majority of these ulcers had always spread from the gastro-jejunal junction. A true jejunal ulcer appeared to be very rare and it was doubtful if it occurred when the anastomosis were performed correctly. It would also seem doubtful if an ulcer could be caused by the trauma due to the use of clamps, for acute ulcers of the stomach tended to heal rapidly, and one would assume that such a lesion in the surface of the jejunum would also heal if no foreign material were present.

(*f*) Hernia through the mesocolon. It was to prevent this complication that advice was always given that the mesocolon be sutured to the junction. He thought that this method of suturing was of more value in preventing slipping of the mesocolon than in preventing such a hernia.

Complications at Present Unexplained.

(*a*) Recurrence of the ulcer. Two groups of this complication might be recognised: (1) Due to faults as described above. In one of his cases in which symptoms recurred five months after excision of an ulcer on the lesser curve, and gastro-enterostomy had not been performed, a posterior ulcer was found at the lower part of the resection, and in the base of the ulcer a piece of silk was found, the recurrence in this case being due to causes similar to those producing a gastro-jejunal ulcer. If a perforated gastric ulcer was sutured, and no gastro-enterostomy were performed, the ulcer was likely to persist or recur. Two such cases occurred in his series. (2) Occasionally, when the technique seemed good, an ulcer might recur. The explanation was difficult to see, but it was possible that the ulcers were present at the first operation and were overlooked, and that they were not cured by a simple gastro-enterostomy.

(*b*) Persistence of the ulcer. An ulcer high up on the lesser curve would probably not be entirely cured by a posterior gastro-enterostomy, and it would be necessary either to excise the ulcer or to perform a partial gastrectomy. If the ulcer were too large or too adherent for this to be attempted the pylorus should be occluded and a gastro-enterostomy performed.

(*c*) Onset of carcinoma. In his experience the percentage of cases in which this happened was very low. It was possible that where carcinoma had apparently supervened after operation it might have been present in the original ulcer. On several occasions when he had performed a partial gastrectomy, on microscopical section a small patch of carcinoma had been seen.

Apart from the complications mentioned, which his figures showed to have been relatively rare, his experience had been that these patients progressed very favourably. He now saw all cases in a "follow through" department, and since it had been started had lost sight of less than 1 per cent. of them. About 80 per cent. of patients with gastric or duodenal ulcers were completely cured of their symptoms. Of the remainder, 3·2 per cent. had one of the lesions described above, which required operative treatment, while the rest showed but ill-defined attacks of dyspepsia, which were easily controlled by short courses of medical treatment.

A Scientific Operation.

Mr. C. RYALL said that the operation of gastro-enterostomy was founded on sound scientific lines and was as free from immediate risks as any simple abdominal operation; disappointing results were, in carefully selected cases, as rare as in other abdominal operations. That gastro-enterostomy cured duodenal and pyloric ulcers, and did so rapidly, was beyond argument. He had seen large inflammatory masses surrounding ulceration disappear, as well as the ulcer, in the course of two or three weeks. Gastro-enterostomy cured ulcers at the pyloric end of the stomach, but he was inclined to excision as well as short circuiting in ulcers away from the pylorus. He wondered whether the fact that some surgeons met with gastro-jejunal ulcers more frequently than others was due to a difference in their technique. Did the ulceration occur more frequently where the opening was small or did it follow any particular method of suturing? Union took place so rapidly, no matter how the suturing was applied, that surgeons naturally fell back on the quickest method of application. He did not favour bunching together all the coats of the stomach, as it did not tend to accuracy of apposition of the mucous membrane, but he considered that better results might be obtained by three layer sutures, a separate one thus being used for the accurate apposition of the mucous membrane. As to the use of thread, he agreed with Mr. Paterson that as a cause of gastro-jejunal ulceration it was unproven, though he himself used catgut for suturing the mucous membrane. He thought that simple ulcers of the stomach and its outlet were due to hyperacidity, and that this was cured and the ulcer healed as a result of short-circuiting; nevertheless, there was no reason why fresh ulceration should not occur, either in the stomach or its new outlet, should hyperacidity recur and remain unchecked.

Dr. A. F. HURST and Mr. G. GREY TURNER also contributed to the discussion.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

ACCESSORY FOOD FACTORS IN INFANT FEEDING.

A MEETING of this section of the Royal Society of Medicine was held on Feb. 27th, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair, when a discussion took place on the Influence of the Accessory Food Factors in Infant Feeding.

Dr. E. MELLANBY, who opened the discussion, touched on some of the more pressing problems concerned with the value of the antiscorbutic factor in infant feeding. It was desirable that authoritative statements should be made on the relative susceptibility of infants to this factor—whether, for instance, there were evidences of ill-health short of scurvy produced by a relative deficiency in the diet. Such symptoms might be widespread, although scurvy itself was uncommon. A point that might also be settled at the discussion was the necessity or otherwise of adding orange or swede juice to diets composed entirely of dried whole milk.

The Antirachitic Factor in Infants.

The rest of his remarks dealt with the part played by the antirachitic factor in infants. He briefly sketched the more recent results of animal experiments on rickets. The following points were discussed:—

(1) The importance of the antirachitic factor in respect to the age of the animal. The younger the animal the more important was a requisite amount of antirachitic accessory factor in the diet. After a certain age it had been impossible to produce rickets in puppies by reducing the antirachitic factor in the diet. Also cases of self cure of rickets in puppies occurred when the diet and other conditions remained constant. These facts showed that the vitamine was more important for the normal growth of bone at an early age, until, in fact, some essential process in the body was in good working order.

(2) The relation of the antirachitic factor to the energy-bearing portion of the diet. It was shown that more accessory factor was required to keep the growth of bone normal when the puppies ate more bread. The offending element of the diet was probably carbohydrate. On the other hand, evidence was accumulating which indicated that additional protein in the diet assisted any antirachitic factor present, so that the production of rickets, so far as diet was concerned, depended on a wrong balance between the amounts of protein, carbohydrate, and antirachitic accessory factor in the diet.

(3) The part played by exercise in the ætiology of rickets. The importance of muscular movements in relation to rickets was discussed and was shown to be secondary to diet. It was pointed out that the effects of exercise and protein could probably be associated in their action of assisting the antirachitic factor by the fact that both were stimulants to the metabolism.

(4) The importance of the animal experimental results to child nutrition. In this connexion the relative amount of rickets and bad teeth in the Jewish and Gentile children of Leeds (1902) according to the investigations of Mr. William Hall were discussed. Mr. Hall's findings as to the cause of the great differences were purely dietetic and wholly in agreement with the expectation based on the animal experiments recently carried out. The low infantile death-rate, absence of rickets, and production of perfect teeth in the inhabitants of the Island of Lewis were then mentioned as being almost certainly due to the diet of the people. The dreadful hygienic conditions of their houses did not prevent these excellent results seen in infant life in the island.

Growth Factors.

Professor D. NOEL PATON said that the physiologist would always be ready to acknowledge his indebtedness to the clinician whose work and observations had suggested to him so many of his most profitable lines of research, and he was trying to repay the debt by applying some part of his time to the solution of problems of importance to the clinician. In doing this it was his duty to present for the acceptance of his clinical brethren only those results which had been thoroughly tested, and he would remember that the man in practice was just as able as he to assess the value of the evidence presented and would not insult his intelligence by asking his acceptance of statements without that evidence being given. The contrary was what he objected to in the attitude of many physiologists to the present craze for vitamines, a horrible name, since we did not know that, even if they existed, they were amines, or had to do with life. Our knowledge of the subject could be briefly stated: 1. Hopkins, Willcox, Osborne, and Mendel had shown that minimal quantities of certain amino-acids were necessary for growth. They were the limiting factors for growth. 2. The same had been shown by MacCollum and others for inorganic substances, chiefly calcium and phosphorus. 3. In various animals it had been shown that the absence of some water-soluble food constituent or constituents led to arrest of growth and death, or to the onset of scurvy or beri-beri. 4. In rats and mice it had been shown that minimal quantities of certain fatty mixtures—e.g., of milk-fat or cod-liver oil—were necessary constituents of the diet for growth. With a deficient supply of these growth was arrested in these animals. In dogs, according to Mellanby, growth was not arrested, but rickets was produced. Of their effect on other animals we knew nothing. On such a basis had we any right to draw far-reaching conclusions? Why did not clinicians arrange a series of experiments in institutions to study the effects of these substances instead of being satisfied with personal experience or remaining content to argue from the divergent results in rats and puppies to the human subject?

Dietary Factors in Rickets.

His own work had been done on rickets and he would confine himself to the evidence that this was a disease due to want of vitamines. In doing so he would refer to the report of the Special Vitamines Committee of the Medical Research Committee. That part which dealt with rickets was certainly a request to accept statements unsupported by evidence. Dr. Leonard Findlay in 1908 reviewed the existing evidence, and recorded a series of experiments upon 16 puppies which he considered proved that confinement and not diet was the determining factor in causing rickets. He found that puppies fed on bread and water simply wasted and died without developing rickets, in the same way that rats wanting the fat-soluble substance wasted and died. All the eight puppies which were kept confined developed rickets; the five not confined, upon the same diet of porridge and milk, did not do so. Mellanby criticised the results on the supposition that Findlay gave only 175 c.cm. of milk, a purely gratuitous assumption. They had an abundance of milk. He further suggested that the diet was not a healthy one because two of the puppies died. It was the diet on which most of the puppies in Scotland were reared. How many of his 200 dogs died? His (the speaker's) criticism of Findlay's experiments was that only in one case were the confined puppies and the checks of the same litter, and it was unjustifiable to argue from results obtained from different litters, since the susceptibility of strains was varied.

The Vitamines Committee's Report.

The report of the Vitamines Committee was avowedly based on Mellanby's results. We could only judge of its value from the results which had been published. These appeared in THE LANCET of March 15th, 1919. He stated that he cleared the way for his dietary experiments by a series of experiments to show that other factors were not operative. These experiments he did not record and we could not estimate their value, but, since then, in a letter to the speaker, he had stated that they consisted in *(a)* repetition of exercises and bad hygienic conditions, poor ventilation, and darkness; *(b)* trying thorium diet; *(c)* removal of lymphatics to limbs; and *(d)* effect of reduction of oxidation by drugs. It was difficult to understand how they were expected to throw any light upon the development of rickets. Upon the influence of the dietary factors he had recorded observations upon 33 pups, 10 normal and 13 which developed rickets. Presumably the experiments selected for publication were not the least convincing of the series. When the records were examined it was found that the dogs grouped together *were not always of the same litter*. To contrast animals of different litters was, as already stated, wholly unjustifiable, since the susceptibility of strains to rickets varied very largely. Further, in his groups the pups were not always killed at the same age, and yet the calcium content of the bones was compared, although, as everyone knew, this varied with age. The same puppy was included in different groups.

In this small series of observations no less than 13 substances were tested, and conclusions were drawn as to which of these allowed and which prevented rickets. In the report of the Vitamines Committee a list of 13 substances which did not prevent and 11 which did prevent rickets was given, with no published evidence except that of Mellanby's paper. Certainly on such a basis it was ridiculous to ask any reasonable man to accept the conclusions (1) that rickets was a deficiency disease due to the absence of an accessory food factor identical with the fat-soluble substance; and (2) that certain specified articles of food prevented its onset, while others did not prevent it.

Professor Paton's Experiments.

The experiments which he (Professor Paton) and his collaborators had carried out, and which were recorded in the *British Medical Journal* of Dec. 7th, 1918, were made upon 17 puppies of two litters. Their main object was to get rickety pups and sound pups of the same litter for examination, but a test was also afforded of the relative influence of diet and open-air life. From each litter two pups were sent to the country, kept in a large yard, and fed upon oatmeal porridge and skimmed milk, so that each had about 2·8 g. of milk-fat per day. Those kept in the laboratory had whole milk containing during the first period of their growth 3 g. of milk-fat per day and during the latter period 6 g. In addition to this, three of the puppies had butter (not margarine) in an amount to yield, along with milk, 14 g. of milk-fat. The puppies kept in the country on the lower fat intake remained absolutely normal. All the puppies kept in the laboratory developed rickets, one of those receiving butter becoming most markedly affected. It had been suggested that puppies kept in the country got their fat-soluble substance by eating grass. Unfortunately for this theory the carnivorous alimentary canal did not digest grass, even when swallowed. It was generally vomited at once. It had further been argued that confinement might so depress digestion that the fat-soluble substance was not absorbed in the food, but there was no indication of disturbed digestion, and Mellanby had stated that confinement did not cause rickets.

In the Vitamines Committee's report no reference was made to Bull's interesting investigations of an epidemic of rickets among fox-hound puppies at Adelaide in 1912.[1] The kennel had previously been free from rickets. The epidemic when it broke out affected practically all the puppies. The animals had been fed on boiled meat and pollard, the only change being that before the outbreak the pollard had been substituted for wheaten meal. He found that the most potent factor in preventing and curing the condition was to remove the pups from the yard in which they had been kept. It was not until a new yard was prepared for the puppies that the occurrence of the disease was prevented, even when the old diet was continued.

Investigations on Negro Children.

The series of investigations which had been given the most prominence was that of Hess and Unger upon negro children in New York. According to the authors about 90 per cent. of these developed rickets. From observations upon 32 children they stated that the administration of 54 oz. of cod-liver oil in six months prevented the onset of rickets in 93 per cent. of the cases. Their tables had been largely used by the champions of the vitamine theory, but it would have been well had they read the paper. Ten out of the 33 children treated had rickets before the oil was administered, and they had merely improved during the six months under oil. As a matter of fact, 6 were noted as "unchanged" and 2 "progressed"—i.e., became worse. This hardly justified the statement as regards the prophylactic action of oil. Miss Ferguson, under the direction of Dr. Findlay, had repeated these observations upon 62 children of from 1½ to 12 months of age, giving them cod-liver oil to about 2 oz. per week (i.e., about the same amount as given by Hess and Unger) for about six months. The cases were examined before starting treatment and were all free from rickets. They were examined again at the end of six months by Dr. Findlay, who reported that out of 27 oil and 30 check cases present at the examination there were:—

	Oil cases.		Check cases.
Non-rachitic ...	23 = 85 per cent.	......	10 = 33 per cent.
Rachitic	3 = 11 ,,	......	18 = 60 ,,
Doubtful	1 = 4 ,,	......	2 = 7 ,,

Miss Ferguson, in 1917, undertook an investigation of the diets and social conditions of families in which rickets occurred and in which rickets had not occurred—47 families in all—of the same social class in the city of Glasgow, where rickets was very prevalent. She found no marked difference in the dietary habits; both sets of families used very small quantities of milk, the average in the non-rachitic families being 6·7 oz. per person per day, and in the rachitic families 4·7 oz. In quite a number of the non-rachitic families the milk consumed was as small in amount as in any of the rachitic. Mellanby criticised these results on the grounds that (1) such family studies throw no light on the feeding of infants, and (2) they show that in the families with rickets the children got less of "substances delaying or preventing rickets." He cannot have it both ways. The criticism of family diets made in the report of the Vitamines Committee that the amount of the proximate principles is given but not the actual foods used is untrue, so far as the Glasgow studies are concerned.

Criticism of the Findings of the Vitamines Committee.

Professor Paton then referred to the most recent publication by Hess and Unger on "The Clinical Rôle of the Fat-Soluble Vitamin; its Relation to Rickets."[2] It was a most cogent criticism of the findings of the Vitamines Committee, supported by a valuable series of observations. They showed that the bone changes in scurvy might simulate those of rickets. They found that rickets developed, notwithstanding an abundance of fresh air. They recorded a series of experiments to show that infants getting abundance of milk-fat became rickety, whilst others kept upon a fat-poor diet remained almost free from the disease. They concluded:

> "It would lead too far afield to discuss the various theories that have been advanced to account for the occurrence of rickets, and, moreover, it would not be profitable at the present time [illegible] the data are inadequate. There seem to be several causes at work rendering the unravelling of the problem so difficult that there is a difference of opinion, not only as to the particular dietary factor that is at fault, but even as to whether rickets is to be considered a disorder of dietetic origin. It should not be lost sight of that there is a prenatal factor

[2] Journal of the American Medical Association, Jan. 24th, 1920.

involved. The fact that the negro infant, living side by side with the white, in the larger cities, and obtaining milk from the same source develops rickets so frequently and so markedly, indicates that there are important influences to be reckoned with in addition to the food. ...... Rickets frequently develops in infants receiving too much milk rich in fats, proteins, and salts. It seems impossible to bring this fact into consonance with a deficiency disease, whatever may be its nature, using this term in the commonly accepted sense. Our study shows that the fat-soluble vitamin is not the controlling influence; that infants develop rickets while receiving a full amount of this principle, and that they do not manifest signs, although deprived of this vitamin for many months, at the most vulnerable period of their lives. It is impossible to interpret the contrary conclusion which Mellanby came to as the result of his pioneer experiments on dogs, or to accept the term 'fat-soluble vitamin' as synonymous with 'antirachitic factor,' as Hopkins and Chick would have us do. ...... There is a growing danger of attributing every unexplained growth impulse to the new attractive, but ill-defined, vitamins—of their sharing with the secretion of the endocrine glands the fate of becoming the dumping ground for every unidentified factor. It should be borne in mind that there are other little understood factors and food reactions."

Rickets had certainly not yet been proved to be a deficiency disease due to the lack of some fat-soluble substance, nor had it been proved to be due to lack of exercise, but it was directly correlated with overcrowding and confinement in insanitary houses. The possibility, suggested by Morporgo, had never been disproved that it was primarily an infective disease. It might be due to non-specific organisms, possibly of fæcal origin, in the same way as goitre had been shown by McCarrison to be due to such infections. Certainly the more scrupulously clean the kennels were kept the less seemed to be the tendency for pups to develop rickets. This was indicated by Bull's observations. What was wanted was a combined coördinated investigation of the disease from the clinical and from the experimental side. Rickets was so prevalent and was of such enormous importance from the economic standpoint that it was well worthy of the most serious study. In the interests of the nation he hoped that the Medical Research Committee would be able to institute such a comprehensive investigation.

Clinical Evidence in Favour of a Dietetic Causation of Rickets.

Dr. ROBERT HUTCHISON said that the causation of rickets had always been a puzzle to clinicians, but up to the present the advent of the experimental pathologist in the field had only served to darken counsel. In his opinion Dr. Mellanby had certainly made out a prima-facie case for the view that rickets was the result of the absence of some accessory substance from the diet, although it did not appear to be the ordinary fat-soluble A. On the other hand, Professor Paton's experiments had led to an opposite conclusion, nor apparently did rats develop rickets when fed on a diet devoid of the growth vitamine. It should further be remembered that Herter[3] had fed young pigs on a fat-free diet for prolonged periods, and although their nutrition suffered they did not develop anything even suggesting rickets. If the results of experiment differed in rats, puppies, and pigs, how could one apply them to babies? Clinical evidence was in favour of the disease being a dietetic one, for it could be cured by altering the diet, the other factors in the environment remaining as they were. The dietetic fault was certainly not an all-round deficiency, for rickets was, perhaps, commoner in overfed than in underfed children. It seemed rather to be caused by an ill-balanced diet, and particularly by one which contained relative excess of carbohydrates. How this caused rickets it was impossible to say, but even Dr. Mellanby was unable to say how the absence of a "vitamine" caused it either. If an accessory substance played any part at all it must be that it was required to counteract some defect in the diet, and not merely that it supplied in itself something that was essential and without which rickets would develop no matter what the composition of the diet was on the whole. The same was true of scurvy. Infants rarely developed scurvy on a diet of condensed milk alone, but if a starchy food were added to the condensed milk scurvy was very apt to appear. The antiscorbutic accessory substance must in some way actively counteract the bad qualities of such a diet and not merely supply something lacking, for it is equally lacking in the condensed milk alone. It might be necessary to assume this kind of action on the part of the accessory substances, but it was attaching to them rather a different rôle from that which earlier investigations had credited them with. He was of opinion that, as regards rickets at least, we wanted more evidence before calling in the action of a hypothetical accessory substance at all. It must be remembered that vitamines were the latest dietetic "stunt"; one must be careful not to push them too far and not to draw sweeping practical conclusions from our present very inadequate knowledge of them.

Dr. C. J. MARTIN thought that from the epidemiology of the disease and clinical experience of the effect of dietetic treatment, there was little room for doubt that rickets was a deficiency disease. Dr. Mellanby's work was of the first importance; it orientated future inquiry. Professor Paton's contribution to the discussion, whilst exhibiting great discontent with the word, was not, in his opinion, a serious assault upon the position taken up by Dr. Mellanby, which was a moderate one. He would underline the remarks of both as to the care required in applying results upon one species of animal to another or to man, and gave the following estimate of the minimal requirements of antiscorbutic in terms of lemon-juice per kilogramme per day as an illustration. These figures had been arrived at by laborious experiments by his colleagues at the Lister Institute. They were as follows: rat, a negligible quantity; guinea-pig, 4·5 c.cm.; monkey, 0·6 c.cm.; man, probably about 0·7 c.cm. In fact, all this vitamine work wanted putting upon a quantitative basis. Until this was done discordant conclusions as to general principles would inevitably be arrived at. Unfortunately, as long as the accessory food factors had not been isolated and identified only an approximate estimation was possible. Anyhow, it would take years of patient labour. For some years it had been attempted by his colleagues and others at the Lister Institute in the case of the water-soluble B and the antiscorbutic principles. This had been of great practical value, especially during the war, for it had been possible to determine the content in a number of foodstuffs of these two vitamines. As an instance he gave the following list from a paper by Dr. H. Chick and Dr. E. J. Dalyell recently published[4] setting forth, weight for weight, the relative antiscorbutic value of some common articles of diet, taking that of lemon-juice as 100.

Fresh raw cabbage leaves or expressed juice	110	Fresh germinated peas	30
Fresh raw lemon-juice... ...	100	,, raw carrot-juice	7·5
,, ,, orange ,, ...	100	,, ,, beet-juice less than	7·5
,, ,, swede ,, ...	60	,, ,, beef-juice ,, ,,	7·5
,, green beans	30	Potato, boiled 30 mins.	7·5
		New cow's milk...	1 to 1·5

Similarly, provided with a rough unit, it had been possible to determine the effect of heating, keeping, and the preservation of food upon these two vitamines with an error of plus or minus 50 per cent.

Orange-Juice and Beef-Suet Cream.

Dr. E. A. BARTON said that he was anxious to show two substances which were being used with considerable success at University College Hospital Infant Department. The first was an orange-juice which was dispensed to all infants on an artificial diet bereft of antiscorbutic vitamine. It was suggested to him by Miss Chick. The orange entire was minced and expressed in a tincture press. The essential oil which existed in the rind served to preserve the juice for many days and even weeks. During the period when oranges were scarce and juiceless he tried last year some vegetable juice freshly expressed, notably that of lettuces, but found that the juice had disastrous results, for the juice of vegetables was a first-rate culture-medium for organisms, and smelt abominably after even a few hours. Preservation or heating was impossible if the vitamine was to be active. It had been suggested that swede-juice should be tried, but poor women had no time to squeeze lettuces or scrape swedes, so during these few months the infants in his hands had to go without. The discovery of an efficient preservative for fresh vegetable juices had yet to be made.

[3] Journ. of Exper. Med., 1893, iii., 293.

[4] Ueber die Gefahr des Skorbuts in Wien, Wiener klinische Wochenschrift, 1919, xxxii., 1219.

The second substance shown was a cream which, being made of beef suet, contained a considerable amount of fat-soluble A. Marylebone cream, made of linseed oil, which he had formerly used, lacked this antirachitic vitamine, and in view of the researches made two years ago, it was decided to make a synthetic beef-suet cream. The difficulty in making suet into a satisfactory emulsion lay in the high melting point of suet, but this was overcome by the addition of 12 per cent. olive oil. The cream contained 25 per cent. fat exclusive of the oil, a percentage as high as or higher than ordinary skimmed cream from milk; it mixed well with all dilutions of milk, was palatable, easily digested, and under the microscope was seen to be quite a satisfactory emulsion. It was not expensive; it was free from danger of tubercle, and was now made commercially as "University Cream." The cream was composed as follows:—

Beef suet	40 oz.	Benzoic acid	35 gr.
Olive oil	5 oz.	Decoction of Irish moss	70 fl. oz.
Syrup...	25 fl. oz.	Water to	1 gal.

The oil was added to the melted suet and the benzoic acid dissolved in the mixture. The decoction was heated to about 60° and placed in the emulsifier, and the fats were then added at about the same temperature. The emulsion was then worked up and the syrup and water were added last.

A Rival Cream.

Dr. ERIC PRITCHARD explained that he had a rival cream to offer which was made from a combination of oleo-fat, pea-nut, and other oils which presented a composition of neutral fats and fatty acids which corresponded very closely with those existing in butter-fat. It was an improvement on the original Marylebone creams, and could be used with fat-free milks without detriment to nutrition, for it contained, he believed, a liberal quantity of the fat-soluble A factor. Dealing with the general question of vitamines, he remarked that there was no fear that the work of Dr. Mellanby and others would not be seriously regarded by clinicians; the danger rather was that the public generally would believe that these new discoveries were the solution of too many dietetic problems. Clinicians would be grateful to experimental physiologists if the latter would help to classify the varieties of malnutrition which depended on excess or deficiency of any food factor; for his part he thought the excess diseases were far more common than the deficiency diseases. He regarded pure cases of the latter as clinical luxuries, because they were so immediately cured by the giving of the lacking food factor. He thought the application of the title antirachitic factor to the fat-soluble A vitamine most unfortunate and retrograde, because such a name implied that rickets could be both caused and cured by the withholding and giving of this substance.

The first group of cases of rickets which he personally had examined was in infants who were grossly overfed with cream. For his part he regarded rickets as a terminal result of practically all varieties of malnutrition occurring in the infant and young child, and of sufficient duration to produce the characteristic changes. Rickets had been proved to be caused by almost every possible error in feeding; it was not due to one definite cause as Dr. Mellanby suggested. The effects of chronic infections certainly played a part in its production, and this, he thought, was the explanation of the cessation of rickets among the puppies referred to by Professor Paton when they were removed from certain particular kennels. He believed that resistance to infective disease was lowered by deprivation of the fat-soluble A factor.

Dr. W. M. FELDMAN was of opinion that there was probably more than one factor responsible for the production of rickets. He disagreed with Professor Paton that close confinement was one of the principal causes of the disease, and also with Dr. Mellanby that the lack of a fat-soluble vitamine was the only factor. He quoted cases of rickets in children of well-to-do and intelligent parents who were brought up on the most hygienic principles as regards fresh air, exercise, and feeding, and who showed signs of rickets, whilst, on the other hand, many children who were brought up under the most unhygienic conditions failed to show evidence of the disease. Dr. Feldman believed that heredity probably played an important rôle.

Rickets amongst Jewish Children.

Dr. J. LAWSON DICK said that he had been carrying out observations with regard to rickets among the Jewish children in the East End of London. These children were fed on cow's milk, yet 80 per cent. of them showed evidence of rickets. It occurred in breast-fed children, many of whom were kept at the breast for from 12–18 months, yet no one could say that there was likely to be lack of fat in the milk where Jewish mothers were concerned. On the other hand, there was no rickets in China or India, where the children were kept for a very long time at the breast, so that even two successive children might be breast-fed synchronously. An ætiology which presupposed a deficiency in fat-soluble substance was contrary to clinical experience, for there was an abundance of fat in children who were prone to rickets. Geographical considerations revealed that rickets was confined to the temperate zone, which was also that of greatest industrial activity. He considered that it was difficult to exclude a sufficient amount of vitamines from the diet of children in this country, while in China and Japan, where they were fed largely on rice, there was no rickets. In experimental observations on dogs it was difficult to exclude the incidence of rickets, but he thought that the changes in the teeth, which had been ascribed to rickets in the experimental studies of Dr. Mellanby, were not the changes of true rickets. He urged that rickets should be studied with a greater breadth of view.

Reply on the Discussion.

Dr. MELLANBY, in his reply, said that the question which Professor Noel Paton had raised as to the number of deaths among the dogs which he had experimented upon was beside the point, whereas the number of deaths among the dogs in the "confinement" experiments of Findlay was important in connexion with the interpretation of the results. With regard to the evidences, he pointed out that the investigations were as yet far from finished, and no complete account had yet been published, but his experiments, as far as they had proceeded, were open to inspection by anyone who wished. He wished to disclaim any responsibility for the exaggerated accounts of the work which had appeared.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this section of the Royal Society of Medicine was held on March 4th, Mr. J. D. MALCOLM, the President, being in the chair.

Interstitial Ectopic Gestation.

Mr. ZACHARY COPE showed a specimen of Interstitial Ectopic Gestation which had ruptured at the end of the fourth month of pregnancy. The patient was 40 years old, and had had three previous pregnancies, which had terminated in miscarriages at the seventh, fifth, and second month of pregnancy. Six years had elapsed since the last miscarriage. Her present illness started with acute abdominal pain and vomiting 36 hours prior to admission. When admitted to hospital ruptured extra-uterine gestation was diagnosed and confirmed at operation. Supravaginal hysterectomy was performed, and the patient made a speedy recovery. The specimen showed a gestation sac about 4 in. by 2½ in. by 2¼ in. with a fœtus corresponding to a three months pregnancy. The left Fallopian tube and round ligament were attached to the outer side of the sac, which had no connexion with the uterine cavity. There was a rupture of the sac on the postero-superior aspect where the placenta was situated. Mr. Cope said that less than a hundred cases of the kind had been recorded. In this case the patient was older than usual, the sac had ruptured rather later than was customary, and surgical advice was sought after a longer duration of acute symptoms than had been noted in most of the recorded cases. In cases seen so late as the fourth month he was of opinion that supra-vaginal hysterectomy was the soundest surgical procedure.

The PRESIDENT said that there was a possible difference of opinion on the interesting case shown. He suspected a cornual pregnancy.

Dr. T. W. EDEN suggested that the specimen should be referred to the Pathological Committee, and that Mr. Cope should obtain sections of the decidua to decide the point.

Mr. COPE thanked the members of the section for the interest shown in his specimen, of which he was having a drawing made, and would be glad to refer it to the Pathological Committee. Microscopic sections were being made.

Dr. S. GORDON LUKER read an account of a case of

Rupture of the Bladder Associated with a Retroverted Gravid Uterus.

The patient, a 4-para, aged 38, was admitted to the London Hospital complaining of acute abdominal pain and vomiting; she stated that she had felt something burst in her stomach that day; there had been a previous attack of abdominal pain with some difficulty in micturition. She was 14 weeks pregnant. Laparotomy was performed and a linear tear 1 inch long was found in the posterior wall of the bladder. The tear was sutured and the abdomen closed with drainage. The bladder was healthy. The patient aborted two days later, but otherwise made an uneventful recovery.

The PRESIDENT said he had never heard of a similar case. The good result showed how efficacious prompt skilful treatment could be, and also of what little consequence a ruptured bladder might be under certain circumstances.

Mr. COMYNS BERKELEY asked whether there was any gangrenous cystitis, as the rupture of a healthy bladder was not common.

Dr. LUKER, in reply, said that the bladder was apparently quite healthy.

Blood Transfusion in Secondary Hæmorrhage.

Dr. LUKER then described a case of Secondary Hæmorrhage from a Laceration of the Cervix Uteri of a Puerperal Woman treated by blood transfusion and panhysterectomy. In this case the patient was a 4-para, aged 30. Labour had been prolonged, and she had been delivered with forceps by her medical attendant before the os uteri was fully dilated. A severe hæmorrhage occurred on the ninth day of the puerperium, and this recurred on the eleventh day; she was then sent up to the London Hospital. On examination under anæsthesia a tear 4 cm. long was seen on the left side of the cervix; the tear was septic but not bleeding; exploration of the uterus was negative; a hot douche was given and the cervix was plugged. Two further hæmorrhages occurred at intervals of about 24 hours, and after the second the patient was almost pulseless. Blood transfusion (1 pint of citrated blood) and panhysterectomy were performed and the patient survived and is now in good health.

The PRESIDENT and Mr. EARDLEY HOLLAND congratulated Dr. Luker on the courageous operation. Mr. Holland also suggested that it might not be clear from the paper that the blood came from a branch of the uterine artery and not from the interior of the uterus. He had had the privilege of seeing the case and knew that the bleeding was from the artery.

Dr. LAPTHORNE SMITH said he had removed a uterus for sepsis 40 years ago, and the patient recovered. In early cases patients did recover with this treatment, but in late cases they died. It was an important field for further investigation.

Dr. EDEN said that the important point was the laceration of 4 cm. long. It was clearly right to remove the uterus.

Dr. H. RUSSELL ANDREWS recalled a patient sent into the London Hospital two days after a four months fœtus had been removed by rapid dilatation of the cervix with Hegar's dilators. The patient had lost much blood. The speaker had removed the greater part of the fœtal skull from the right broad ligament. After 48 hours a secondary severe hæmorrhage nearly killed the patient. He put in plugging; the patient developed a mass in the right iliac fossa, chiefly cellulitis and not hæmatoma. Another hæmorrhage 48 hours after made him debate whether to remove the uterus, but he was doubtful if the patient would survive the operation. However, no more bleeding occurred.

Dr. LUKER, in reply, regretted that various points had not been made quite clear. The tear in the uterus was septic at the first examination, and later a spurting artery was actually seen in the cervix. There was no possibility of suture owing to the sepsis.

Mr. GORDON LEY read a paper on an Analysis of 50 Cases of Utero-placental Apoplexy (Accidental Hæmorrhage).

TUBERCULOSIS SOCIETY.

THE NEED FOR A DIPLOMA IN TUBERCULOSIS.

AT a general meeting of this society held on Feb. 21st, Dr. H. DE CARLE WOODCOCK, the President, being in the chair, Dr. HALLIDAY SUTHERLAND opened a discussion upon the Need for a Diploma in Tuberculosis. He said that, as in other specialised branches of medicine, the public should be protected against inefficiency by fixing a minimum of knowledge in tuberculosis as essential for holding responsible positions in the health service of the country. It was not sufficiently recognised that tuberculosis entered into every phase of life from early youth to old age, and this scant attention had resulted both in faulty and late diagnosis. This state of affairs must be changed before any real progress could be made in the campaign. Little was taught and but little required in a student's passage through the ordinary degree for medicine, and in the curriculums of most schools only two or three lectures at most were given and no practical experience exacted. Dr. Sutherland referred to the recommendations of the Interdepartmental Committee of 1912, and deplored the fact that the most important of these had never been put into effect. He considered that practitioners should attend dispensaries both for study and help; that dispensary teaching should be brought into every medical school; that tuberculosis officers should have had general and special experience before their appointment; that tuberculosis workers should have at least one month's post-graduate study in every three years. These suggestions were all embodied in the Committee's report, and they would go a long way to overcoming the present difficulties. A great deal of harm was done by men going into the tuberculosis service who did not gain the confidence of the general practitioner, which was so essential, with resulting lack of uniformity of methods and records. The sanatorium and dispensary have not failed in principle, but rather the personnel has been found wanting. There were too few places at which a proper course of instruction in tuberculosis could be obtained; Edinburgh had the only chair and Glasgow the only demonstratorship in tuberculosis; the number of teaching centres should be increased and the course should consist of at least 40 lectures, with practical demonstration. He thought that the teaching would be more successful if at the end of the course there was a diploma to be obtained, constituting a hall-mark, which local authorities might demand of applicants before appointment.

Discussion.

The PRESIDENT thought a diploma essential; it would settle the dispute with the medical officers of health. He had tried to get tuberculosis brought more into the curriculum of the University of Leeds, but had failed, and considered that public opinion must be sought in order to get recognition of its importance.

Sir HENRY GAUVAIN said that there were officers at present holding responsible positions in sanatoriums who had never seen the inside of a dispensary, and the converse could be said of some tuberculosis officers. Many men who had been down to Alton admitted that they did not know that they ought to be familiar with surgical tuberculosis.

Dr. J. SORLEY opposed the proposal for a diploma, but considered that the Interdepartmental Committee's recommendations should be put into force. He was not in favour of picking out one disease more than another, and thought that the D.P.H. should embrace all subjects of public health. If not the D.P.H., then the M.R.C.P. would give the necessary status and confidence.

Dr. HORACE WILSON thought tuberculosis too big a subject to be included in the D.P.H., and that a diploma was needed to prevent unsuitable men from throwing discredit on the service.

Dr. NATHAN RAW, M.P., said that tuberculosis demanded the widest study, and the tuberculosis officer must have long clinical study to fit him for his work. He did not think the time was ripe for a special diploma, but the interest of medical schools should be obtained and teachers should be appointed. When this was done, and the men had been taught, the diploma would come as a matter of course. The Medico-Psychological Society had at one time created a diploma, but had failed to enforce it. He did not think it would be long before there was a separate department in the Ministry of Health for tuberculosis.

Dr. HALLIDAY SUTHERLAND replying, agreed that the diploma would help to settle the outstanding differences with the medical officers of health, and would work in the direction of a separate service. Theory was not enough to produce efficiency, but practice would develop better on a sound theoretic basis.

LIVERPOOL MEDICAL INSTITUTION.—At a meeting of the Pathological Section held on Feb. 20th, with Dr. J. E. Gemmell, the President, in the chair, Dr. R. Stenhouse Williams read a note on the Bacterial Content and Keeping Qualities of Clean Milk Produced for Commercial Purposes. He presented the results of work upon methods of milk production which had been carried out by Miss K. Freear and Miss F. Knight at the Research Institute in Dairying at University College, Reading. A series of weekly examinations of clean-bottled milk produced for commercial purposes, extending from November, 1916, to December, 1918, demonstrated that the bacterial content of such milk only rose above the 10,000 limit on three occasions, and was only really unsatisfactory in one instance. These results were obtained with milk taken in a special milking shed from washed cows, by clean workers, in steam-sterilised vessels. The cost and upkeep of a special milking shed was an added charge on the price of milk, and further experiments were detailed which demonstrated the possibility of producing clean milk in an ordinary cow byre. From these experiments the following facts emerged: (1) it was possible to produce clean milk in an ordinary cow byre; (2) to ensure success the cows should be clipped and washed, the workers clean, and the utensils steam-sterilised; (3) the covered milk bucket, when properly used, was of great assistance in keeping out dirt from the milk, but, in the hands of unskilled workers, might be an added source of contamination to the milk. Dr. Williams laid stress on the importance to the dairy farmer of this last observation. Dr. Williams further contributed a paper on the Presence of Tubercle Bacilli in the Fæces of Apparently Healthy Cows. He recorded an investigation carried out by himself, in collaboration with Mr. W. A. Hoy, on behalf of the Medical Research Committee. It was shown that about 2 per cent. of apparently healthy cows had been found to be excreting tubercle bacilli in the fæces. Five such cows had been found in four of the 14 farms in which it had been possible to examine the fæces of nearly all the cows in milk. The results were subject to a considerable margin of error, inasmuch as each cow was examined on a single occasion, only a very small fraction of the daily excreta could be tested, and the method of examination (antiformin) adopted in the earlier stages of the work did not appear to be so satisfactory as the method (Petroff) finally utilised. He showed that the excreta of such cows, when kept in a dark cellar, remained infective for at least 12 months, and, when spread upon pasture land or added to liquid manure, remained infective for at least four months. The possible influence of such material upon the health of other beasts in the farm was pointed out.—Both note and paper were copiously illustrated by charts.

Reviews and Notices of Books.

HISTORY OF THE GREAT WAR: NAVAL OPERATIONS.

Vol. I. Based on Official Documents. By Direction of the Historical Section of the Committee of Imperial Defence. By Sir JULIAN S. CORBETT. London and New York: Longmans, Green and Co. 1920. Pp. 470 and maps. 17*s.* 6*d.*

THE first volume of the History of the Great War in regard to naval operations has been issued this week, written by Sir Julian S. Corbett. The history is based on official documents to which the Lords Commissioners of the Admiralty have given access, though the presentation of the facts is, of course, the author's own. The period dealt with includes the preparations for war during the years immediately preceding the outbreak of hostilities, and the progress of the naval operations down to the time when Great Britain secured a working command of the ocean trade-routes by the Battle of the Falklands on Dec. 8th, 1914. The work is written in collaboration with the staff of the Historical Section of the Committee of Imperial Defence, and it is hoped will be complete in four or five volumes. Separate sections will appear on the effect of naval operations on seaborne trade, by Mr. C. E. Fayle, and on the Merchant Navy by Mr. Archibald Hurd.

The time-period covered by this large and important volume is comparatively short, if we except pre-war references, but Sir Julian Corbett has been at pains to explain the mutual connexion and meaning of the operations which he describes, as well as their policy and relations to diplomatic activity and military exigencies. In this way we obtain a full and satisfactory narrative, which could not with advantage have been abbreviated to make the size of the book proportionate to the time concerned. The story, as he sets it out, is one of high endeavour, great performance, and hideous disappointments, as well as of national courage and enterprise which rose superior to these disappointments.

The style is so admirable in its clearness, and the events so sharp with interest, that most readers will read the book from cover to cover, even though first turning to such chapters as those which describe the development of the German submarine tactics, the operations of our Fleet on the Belgian coast, or the exploits of the *Karlsruhe*, *Emden*, and *Koenigsberg*. At last we have a consecutive story of the location, chase, and escape of the *Goeben*, described by Sir Julian Corbett as a situation which "opened in so promising a way that it might well have resulted in a success priceless at the outbreak of the war," but which culminated in severe disappointment. He considers that the whole blame did not rest on the shoulders of the admiral, rapid changes in the situation making it impossible for the Admiralty to keep him adequately informed. But of the fact that the *Goeben* was able to enter the Dardanelles in safety, Sir Julian Corbett, speaking of German tactics, says: "So completely, indeed, did the risky venture turn a desperate situation into one of high moral and material advantage, that for the credit of German statemanship it goes far to balance the cardinal blunder of attacking France through Belgium." Such episodes as the Gorleston raid, the crossing of the Pacific by Admiral von Spee, and the closing chapters narrating operations leading up to the Battle of the Falklands will be read with the deepest interest.

Practically nothing is said about the naval medical establishment, but the medical history of the war is appearing in the *Journal of the Royal Naval Medical Service*.

In a separate case with the book are published maps and charts illustrating some of the episodes where such assistance is necessary to their comprehension, while the volume itself also has admirable maps, plans, and diagrams, the Battle of the Falklands being elaborately explained by their means.

A GUIDE TO GYNÆCOLOGY IN GENERAL PRACTICE.

Second edition. By COMYNS BERKELEY, M.A., M.D., M.C. Cantab., F.R.C.P. Lond., Obstetrical and Gynæcological Surgeon to Middlesex Hospital, &c.; and VICTOR BONNEY, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., M.R.C.P. Lond., Assistant Obstetrical and Gynæcological Surgeon to Middlesex Hospital, &c. London: Henry Frowde. 1919. Pp. 467. 31*s*.

THIS book is written for the practitioner to assist him in supplementing the knowledge of his subject, obtained during his studentship, with a practical understanding of its clinical intricacies. The subject-matter is arranged in a natural sequence: Part I. is occupied with Examination Methods; Parts II. and III. with a consideration of the Significance of Symptoms and the Interpretation of Physical Signs; and in Part IV. the various Methods of Treatment are described. In Part V. a very full account of the Medico-legal Aspects of Gynæcology is included, and this is one of the most useful sections in the book. It is a subject at times of considerable importance to the practitioner and one upon which there is very little in the ordinary text-books of forensic medicine to guide him when in difficulties. All the questions associated with such conditions as nullity of marriage, rape, criminal abortion, evidence of pregnancy, foreign bodies left in the abdomen and other cavities, and possible claims for compensation in connexion with gynæcological conditions are fully considered, and sound advice is given.

The arrangement of the whole work is particularly useful and the various symptoms and physical signs are discussed in very complete detail, so that there is no condition likely to be met with in a gynæcological case about which the practitioner will not obtain real help and guidance from this work. In the new edition the part dealing with Criminal Abortion has been exhaustively revised, and sections on Radium and X Ray Treatment have been added. The authors have duplicated their prescriptions according to the ingenious method suggested by Dr. Verdon Roe. He has pointed out that the figures indicating the number of grammes and cubic centimetres in a prescription for 15 doses are the same as those indicating the number of grains and minims for a single dose according to the English system. We notice one or two obvious misprints in these prescriptions. The illustrations are very good and well reproduced. We could not, however, agree with the method of bimanual abdominal palpation as represented in Fig. 16, as the whole essence of successful abdominal palpation is the use of the palms of the hands and not of the tips of the fingers. Why, we wonder, do the authors use the unusual term, "palpation nephroleptique?"

It is interesting to find the statement that dilatation of the cervix cures some 90 per cent. of cases of spasmodic dysmenorrhœa, while in another well-known and widely read English text-book on gynæcology we are told that this operation is practically useless for this condition. A considerable space is devoted to the advantages of enucleation of fibroid tumours; in this we fancy the author's teaching is opposed to that of the majority of English gynæcological surgeons. The book is arranged in a distinctly novel manner, is interesting to read, and should prove of great service to the practitioner.

TOXINES ET ANTITOXINES.

Par M. NICOLLE, E. CÉSARI, C. JOUAN. Paris: Masson et Cie. 1919. Pp. 123. 5 francs.

AS we gather from the preface, this monograph is a résumé of a large number of original articles contributed to French scientific journals over a period of many years, by the authors whose names appear on the cover of the book and by some of their colleagues. The complete bibliography of these occasional articles is given in the front of the monograph before us. The work itself is a simple, lucid account, systematically arranged, of toxins and their antibodies. There are no laboratory details and no discursive accounts of theories. The first half of the book deals with the principal characteristics of toxins, both "soluble" and "solid" (i.e., filtrates and bacteria respectively). The second half deals with hypersensitiveness, anaphylaxis, the various antibodies, &c., and closes with a comprehensive chapter on the general conception of antigens and antibodies.

The book is written on an essentially personal note expressing the views of the authors. It is, moreover, characterised throughout by a clarity of thought and by a systematised arrangement of text which other writers on immunity might very well copy. In common with many others of these admirable little French monographs the work contains no subject index.

THE ENGINES OF THE HUMAN BODY.

By ARTHUR KEITH, M.D., LL.D., F.R.S. London: Williams and Norgate. 1920. Pp. 284. 12*s*. 6*d*.

THIS book contains the substance of the lectures which Professor Keith delivered at the Royal Institution during the Christmas vacation, 1916–17. From first to last the structure and functions of the various parts of the human body are compared, very closely and ingeniously, to the creations of the mechanical engineer. Several writers have drawn comparisons between the human body and an engine, but few have attempted to carry the comparison so far, and none have proceeded to interpret in such a clear and fascinating manner the details of function which Professor Keith has incorporated into this interesting story.

It is a great achievement to overcome so simply one of the chief difficulties in teaching popular anatomy—in the absence of information derived from dissecting, to make clear the mechanism of the numerous activities of all the systems and their inter-relationship, without obscuring the issue by lengthy descriptions and collections of facts about the details of structure. On this point teachers of anatomy in our medical schools have much to learn from Professor Keith, since only too frequently instruction in anatomy consists of a vast accumulation of data with little or no regard to the bearing of structure upon function. "The Engines of the Human Body," although written chiefly for the general reader, indirectly demonstrates the advantages to be gained by anatomists ceasing to be mere purveyors of fact about the cadaver; it furthermore contains many suggestions for the attainment of this improvement. Popular anatomy has to refer to the living; it is obviously of even greater importance that anatomy for students of medicine should do so too.

We therefore suggest that this book may be read with advantage, although for different reasons, by the anatomist as well as the general reader. However ingeniously popular anatomy may be presented it must inevitably have very definite limitations, which emphasise the importance of familiarity by dissection with the organs and tissues of the body. When considering the teaching of popular anatomy it is always apparent that no description, illustration, or even model can replace the method of acquiring, by the senses of sight and touch, an accurate knowledge of the subject and a true sense of proportion.

THE FROHSE ANATOMICAL CHARTS.

American edition. London and Edinburgh: W. and A. K. Johnston; Chicago: A. J. Nystrom and Co. Seven plates, each 42 in. by 64 in. Price, complete, mounted on cotton, £11. Single plates £1 10*s*. each.

THIS well-known series of plates has been redrawn and revised by Professor Max Brödel, of Johns Hopkins Medical School, who has also added some new diagrams of the heart and circulatory system and of the internal structure of the ear. The seven plates of the new series contain respectively (1) the human skeleton; (2) muscles; (3) nervous and circulatory system; (4) circulation diagram, the heart, blood-vessels, skin; (5) the ear and the eye; (6) the viscera; (7) the teeth and section through the head. Most of the drawings are life-size, and in many cases separate organs and tissues are shown greatly magnified. A key is supplied giving a comprehensive list in Latin and English of the various parts of the body. The lithographing and colouring are admirably done, and there is advantage in the arrangement which enables comparison to be made between related subjects.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES.

By E. R. STITT. Third edition. London: H. K. Lewis and Co., Ltd. 1919. With 119 illustrations and 1 plate. Pp. xvi. + 534. 14*s.*

THIS book has now reached its third edition and may be consulted with advantage by all students of tropical medicine. It will be found to contain a mass of interesting material, fairly well up to date and instructive. Much has recently been written on diseases of a tropical nature, but even so it is extraordinary how little that is new has really been evolved. The treatment of malaria, for example, stands at the present moment much where it stood 20 years ago, while dysentery has been written on ad nauseam without any proportionate light being thrown upon its therapeutics. There is a tendency here and there in the book to ignore older work for more recent observations, a fault which might have been avoided by a closer study of the literature. This is specially noticeable in the parts dealing with filariasis and ulcerating granuloma. No mention is made of the work of the South Americans and of Low and Newham on the treatment of the latter disease with intravenous injections of antimony, though Breinl's name is mentioned. On the other hand, the dysentery treatment is quite out of date. Emetine bismuth iodide is not even mentioned, and none of Dobell's recent work on the amœbæ inhabiting the intestine of man is incorporated in the text.

SPRING-TIME AND OTHER ESSAYS.

By Sir FRANCIS DARWIN, F.R.S. London: John Murray. 1920. Pp. 242. 7*s.* 6*d.* net.

Sir Francis Darwin is known as a skilled botanist, and as one who worthily carries on the traditions of a family which has produced more able men of science than perhaps any other single family in the world. He was educated for the medical profession, and got as far as taking his M.B. degree at Cambridge, but at the suggestion of Dr. Klein he gave up further study of medicine and became assistant to his father.

The book now before us is a very good sample of that class of book which used to be called "Diversions of a ——" or "Idlings of a ——," the blank being filled up according to the profession or calling of the author. On the whole, we think that the botanical or quasi-botanical papers show the author at his best. Many of the essays are reviews, or what are apparently reviews, though they consist chiefly of excerpts from the books in question. One particularly charming paper is entitled "Recollections," its only fault being that there is not enough of them. Another deals with Sir Norman Moore's monumental History of St. Bartholomew's Hospital, which should certainly send any reader to the original. Yet a third talks pleasantly about Some Characters in Fiction. Sir Francis Darwin, we think rightly, gives the palm to Thackeray for the names of his characters, only we do not always agree with his choice. For instance, he is "particularly fond of Sir Lapin Warren, whose wife was just on the point of having her thirteenth child"; and also of the Revd. Felix Rabbits, who had 13 daughters. To our thinking these names savour too much of the harlequinade nomenclature of the old-fashioned pantomime. Everyone over 50 will remember the names of A. Pill, Chemist, or D. R. Y. Sand, Grocer, which used to appear on the back cloth. One of the best collection of Thackerayan names is the list given of guests as yelled by the usher in "A Dinner in the City" thus, "Mr. Hoggin! The Right Honourable the Earl of Bareacres! Mr. Snog! Mr. Braddle! Mr. Alderman Moodle! Mr. Justice Bunker! Lieutenant-General Sir Roger Bluff! Colonel Tucker! Mr. Tims!" They are so exactly the names that are heard on such occasions, and the rhythm of the collocation is perfect. But the cream of the book is to be found in the three essays dealing with plants—namely, "Spring-time," "The Traditional Names of English Plants," and "A Procession of Flowers." Here are the charm of the country, the knowledge of the skilled botanist, and a picture of the never ceasing wonder of the annual renewal of life.

HOME EXERCISES FOR SPINAL CURVATURES.

By R. TIMBERG, M.R.C.S., G.D. (Stockholm). Second edition. London: W. Heinemann (Medical Books), Ltd. 1920. Illustrated. Pp. 67. 6*s.* net.

THIS little book has a definite object, and the author wisely keeps that object in mind from beginning to end. The theme being the description of certain exercises, all extraneous matter is ruled out, save that which is essential to the proper understanding of them. The exercises are well selected from those in use in the department for physical remedies at St. Thomas's Hospital; they are described with precise detail and illustrated by a series of well-executed photographs. No attempt is made to theorise on spinal curvature or to discuss the relative merits of various forms of treatment. All reference is omitted to exercises which cannot be performed without help or, after preliminary instruction, without supervision. Thus the book is elementary and, as such, is just what is needed. The treatment of spinal curvature is of great importance. Children do not "grow out of it"; if disregarded it becomes progressively worse. Skilled treatment is essential, but success depends on voluntary effort at home between the periods of skilled help and instruction. It is to enable medical men and parents to guide this voluntary effort into proper channels that this book was written, and it will be found a sure and safe guide.

PRAKTISCHE BAKTERIOLOGIE.

Für Ärzte und Studierende. Von Dr. L. PANETH. Berlin and Vienna: Urban and Schwarzenberg. Pp. 158. 1920. M.8.

THIS small volume is an elementary introduction to practical bacteriology. It gives short accounts of ordinary bacteriological and serological technique, the preparation of media, and the different methods of staining bacteria. A special feature is made of the methods of isolating and identifying the organisms of typhoid, dysentery, and cholera. The main characteristics of the commoner organisms are described, and a description of the Wassermann reaction is included. The book is well printed. There are few illustrations.

THE FOUNDATIONS OF MUSIC.

By HENRY J. WATT, D. Phil. Cambridge: University Press. 1920. Pp. 240. 18*s.*

THE scope of Dr. Watt's book lies beyond the realms of physics and of physiology. He deals solely with the psychical appreciation of musical sounds, and does so ingeniously, profoundly, and with a measure of success. The foundations which he has laid stand in the darker recesses of musical theory, and involve assumptions which themselves call for extensive and detailed examination before they can be accepted as a basis for the further arguments. But for those with sufficient musical knowledge and interest in the theory of music, and with the capacity for hard and sustained psychological speculation, the book will well repay careful study. It is a real contribution to the systematic investigation of the psychology of one of the most obscure special senses, for the musical sense may be considered psychologically as something altogether beyond the sense of simple hearing.

JOURNALS.

British Journal of Experimental Pathology. Vol. I., No. 1. February, 1920. London: H. K. Lewis and Co., Ltd. Annual Subscription, £2; single numbers, 7*s.* 6*d.*—This is the first number of a new journal devoted to experimental pathology. It is to be published bimonthly, under the editorship of Drs. C. H. Browning, P. Fildes, W. E. Gye, E. L. Kennaway, E. H. Kettle, J. McIntosh, J. A. Murray, W. J. Tulloch, and C. M. Wilson. The editors hope to be able to provide early publication of papers, a boon to workers in pathology, who have long felt the disadvantages of delayed publication of their work. The journal comprises many new and interesting features—new at any rate in British scientific journals. It provides space, for example, in each issue for a short description of new methods or neat "tips" which would not ordinarily be printed as a "paper"; it promises the occasional publication of critical reviews upon pathological subjects which, in the opinion of the editors, may be in need of critical survey. This, if competently and fairly done, will render the journal of inestimable value to laboratory workers and, one might add, to clinicians who take any interest in the growth of exact knowledge. The editors stress the word experimental in the title of the journal as well as in their notice of the scope of papers to be published. It appears, therefore, that the purely descriptive work of morbid anatomy will be left to be dealt with by existing journals. A natural consequence of this attitude is found in the close association of some of our leading physiologists with the journal; of the 16 eminent medical scientists whose names appear on the cover as supporting the new venture four are famous physiologists. But, curiously enough, there is not one professional physiologist in the list of editors. This will no doubt be altered in the future.

W. M. Bayliss, F.R.S.: Is Hæmolysed Blood Toxic? Professor Bayliss discusses this question and brings forward evidence to show that hæmolysis in itself is harmless. The practical importance of the matter lies in the common belief that "the serious results of transfusion of blood into a patient whose blood hæmolyses the corpuscles of that introduced" are due to the hæmolysis. The experiments upon which the belief that hæmolysed blood is toxic have been performed with rabbits. Professor Bayliss points out that rabbits are not suitable animals for such experiments owing to their aptitude to intra-vascular clotting. In the cat and dog homologous hæmolysed blood is, with very rare exceptions, innocuous. The ill-effects occasionally noted in blood transfusions are "an aspect of the action of foreign serum protein analogous to that responsible for anaphylactic shock." It is shown in the paper that hæmoglobin dissolved in plasma can act as an oxygen carrier.—The Determination of the Reaction of Bacteriological Culture Media, by J. McIntosh, M.D., and W. A. M. Smart, B.Sc. This is now one of the most popular subjects of bacteriological research. The method of standardising by titration, using phenolphthalein as indicator, and of expressing the final condition of the medium by the simple device introduced by Eyre, is no longer regarded as sufficient. The majority of bacteriologists now endeavour to obtain a more exact standardisation, either by means of the hydrogen electrode or by the use of a scale of indicators, which change colours at definite concentrations of hydrogen ions. Colorimetric methods are generally favoured, and have been recently popularised by the Medical Research Committee. In the paper under notice the authors propose titration of small volumes of media at room temperature. They recommend thymophthalein as indicator owing to the sharpness of the change of colour at a point on the alkaline side of neutrality. The paper contains a clear account of simple methods of preparing reliable media. The discussion of the ionic theory, mass action, and Guldberg and Waage's law might have been omitted; a reference to a standard text-book would have sufficed.—On Sympathetic Fever and Hyperpyrexial Heat Stroke, by W. Cramer. When suitable doses of β-tetrahydronaphthylamine are injected into animals, prolonged sympathetic stimulation associated with over-activity of the thyroid - adrenal apparatus is produced. Pyrexia is induced by increased heat-production accompanied by diminished heat loss; this pyrexia is called by the author sympathetic fever. The degree of pyrexia is chiefly dependent upon the climatic conditions of environment. Hyperpyrexia may be brought about by over-crowding the animals or by any means which interferes with the rate of cooling. This hyperpyrexia is similar to heat-stroke in man, which is discussed both as to its genesis and its rational treatment. The paper is full of information on the subject and is closely reasoned. It should be of particular value to those interested in ventilation and in factory and tropical conditions.

The Serological Classification of Meningococci, by P. Fildes, M.B. The author shows that meningococci may be divided into two distinct serological groups, independent of the arbitrary selection of standards.—On the Testing of Renal Efficiency, with Observations on the "Urea Coefficient," by H. Maclean and O. L. V. de Wesselow. Dr. Maclean has previously shown that in 50,000 apparently fit soldiers protein may be found in the urine of nearly 6 per cent., and that 2 per cent. show well-marked albuminuria. The presence of albumin, even when associated with casts, is not of great value as an indication of renal efficiency—the most important point the clinician has to decide in cases of renal disease. In this paper the authors describe in detail a simple and beautiful method of testing the efficiency of the kidneys. It is used by the Ministry of Pensions in the assessment of a patient's condition. A general scheme for the examination of renal conditions is given, which should be of great value to both physicians and surgeons.—Dr. Alexander Fleming and Dr. Francis J. Clemenger describe a simple method of recording gas production and oxygen absorption by bacteria in culture.—Dr. McIntosh gives a description of the simple preparation of a litmus solution suitable for bacteriological purposes.

New Inventions.

A NEW HEAD-LAMP.

THE lamp (Fig. 1) is on the well-known Klar principle, but with a reflector of speculum metal, so that it cannot break, and of sufficiently small size to allow of very useful peripheral vision when in place. The eye-holes are very large and placed on the converging lines for near binocular vision. The reflector (Fig. 2) is attached to a rigid head-band by an arm with an adjustable hinge at either end, permitting of movement only in the saggital plane. The lamp can thus be adjusted before washing up, and then brought down into place or pushed away from the face with a mop, no readjustment being needed, and no breach of asepsis being entailed. An automatic switch cuts off the current when the reflector is out of use, thus enabling it to be used off a pocket battery in the ward or clinic without waste. The front part of the head-band is sloped back through 15°, an angle which causes it to lie flat on practically every forehead and permits of the lamp being worn for long periods without discomfort. I have found the lamp useful not only for ear, nose, and throat work, but also for many operations in general surgery where the general illumination available was insufficient.

FIG. 1.

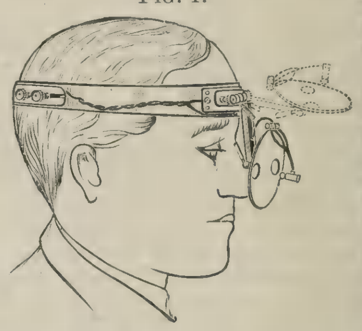

FIG. 2.

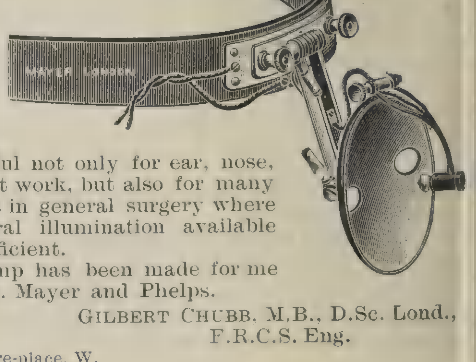

The lamp has been made for me by Messrs. Mayer and Phelps.

THE LANCET.

LONDON: SATURDAY, MARCH 13, 1920.

The Future of the Voluntary Hospitals.

AT the present moment changes and developments closely affecting the profession of medicine may be regarded alike as a consequence of the world war, as a sequel to the institution of a Ministry of Health, and as a development of National Insurance. Each factor affects the voluntary hospitals, on which falls a share of the sad burden conferred on us by the broken warrior, at a time when international disorganisation has made poverty in money and scarcity in supplies a world-wide condition. The hospitals, founded by ancient charity for the medical relief of the poorer classes, are inextricably bound up with the training and the progress of our profession, and all that affects medicine must affect simultaneously the position and conduct of the voluntary hospitals. It seems to be assumed widely that the day of the voluntary hospital is over, and this despite official assurance that no despatch of the sort will be expedited by the Ministry. The direction which social evolution may take is another matter. A public willing to coöperate in order to bring about a more extended usefulness of medicine and of hospitals will play a part in such evolution, and laymen will no doubt be ready to be guided by the medical profession in their views as to the value of the voluntary system. For certainly this system is an expression of altruism on the professional side. The public should feel that if, in charitable guise, they bear the cost of institutions whose funds in practically no case bear any relation to their necessary expenditure, they also form the patients the preservation of whose health is aimed at. In the voluntary hospitals the public have good value in return for their expenditure. The charitable few, whose generosity in past times has founded individual hospitals, have their analogue in charitable thousands to-day, and these will not willingly let a system pass away so fraught with benefit for all. And yet the system no longer meets the national case. We remind our readers of the somewhat similar position which marked the evolution of our national system of education in 1870 and 22 years later. The difficulty in the framing and modification of the Education Acts was to secure public control, as a necessary concomitant of public maintenance, without destroying the special, or religious, character of the voluntary schools. The difficulty has been fairly well surmounted by a policy represented in the phrase "supplement and not supplant"; and this is the direction in which a solution of the hospital question may be expected.

For the development of medical and surgical science, and of our knowledge of the causes of disease, work done in the voluntary hospitals has been responsible, but the institutions have had laid upon them too heavy a burden. The education of medical students would be impossible without the hospitals, but thus there is added a load greater than the founders could ever have dreamed of. Coupled with all this comes an increasing recognition of medical science on the part of the general public. The demand for, and general acceptance of, National Insurance were symptoms of this appreciation, which the feats of medicine and surgery in the war have stimulated. So far as the hospitals are concerned, the result has been an increased demand for accommodation within their walls, quite apart from the number of those for whom institutional treatment is admittedly needed as a sequel to naval or military service. Mr. E. W. MORRIS, House-Governor of the London Hospital, in some interesting articles contributed recently to the *Daily Telegraph*, emphasised the fact that the hospitals of London are already overcrowded, and have long waiting lists of poor patients, whose admission has to be postponed till there are beds vacant for them. To these a host of persons in need of treatment can be added, who are not less poor than the manual worker, but are not in the ordinary sense objects of charity; and to these the doors of the voluntary hospitals are closed. Nor can they afford highly skilled surgical or medical assistance in nursing homes, at what, for want of a better phrase, we may call "market prices." This amounts to a plea for paying hospitals of various grades, and the day is gone by when the general practitioner would see any unfair rivalry in such institutions, for he himself would have the care of his patients, advising them what special assistance, if any, should be summoned. At the London Hospital a paying system has now been inaugurated, to run alongside of the gratuitous reception of the entirely needy. The step was taken, with the approval of the governing body, in view of the urgent money situation, but it can only be regarded as a move to meet a special case. The solution of the financial problems of the voluntary hospitals does not lie in any direct payments by the patients, if only because those payments would be required of them at the moment when they would be least able to meet them.

Developments of institutional treatment are likely to be demanded and carried through which will be beyond the means of the voluntary hospitals as now constituted. The question will then arise, when legislation seeks to provide for such progressive changes as the nation may desire, whether the voluntary hospitals are to be absorbed into a new system, or whether they are to retain as far as possible their former position, characteristics, and functions. An equally important question for those who desire to see them enjoying continued existence, with increased vitality and usefulness, will be whether voluntary charity will continue to support hospitals side by side with institutions doing similar work, but created and sustained out of public funds or by means of insurance, or by a combination of the two. We have to contemplate such institutions, and such insurance as we now refer to, as designed to include classes not yet found in our hospitals or subject to existing Insurance Acts, when the matter of the remuneration of the professional staff comes into the area of discussion. Will physicians and surgeons give their services as they now give them, rewarded by the knowledge that they are helping their fellow-men in need, and training their juniors; will they be content with such indirect advantages as are to be derived from their position and their hospital practice? In asking this we are assuming the possible existence of voluntarily supported hospitals contemporaneously with others open to a wider clientèle, founded and governed by the State, and presumably paying their staffs out of public funds. The whole position calls for much thought, and we trust that the Medical Consultative Committee of the Ministry of Health, in its imminent report, will deal with the issues in a practical, and especially in a far-seeing, manner.

The Story of Salvarsan.

Two recent reports (Nos. 41 and 44) of the Medical Research Committee deal with the organic arsenical compounds. No. 41 is divided into two sections, the first being devoted to the ultimate results of the treatment of syphilis with these products, and the second to the toxic reactions which may follow the administration of one of them, Ehrlich's "914." The observations on which this report is based were made at the Royal Naval Hospital Haslar, under the direction of Dr. P. FILDES and Dr. R. J. G. PARNELL, R.N., who have put to good public use the remarkable facilities at their disposal for obtaining valuable data, and for observing the results of treatment. Their memorandum will be read with profit by all those engaged in venereal work for its estimate of the arsenical treatment of syphilis based upon direct clinical observation of results.

From the national point of view No. 44 is of special interest, being the product of the deliberation of a special committee appointed to consider the manufacture, biological testing, and clinical administration of salvarsan and of its substitutes. Before the war the manufacture of salvarsan was in the hands of a single German firm, which was under the obligation to submit batches of the drug for testing under EHRLICH'S direction at the Georg-Speyer Haus, Frankfort. After the outbreak of hostilities a sufficient supply of German salvarsan could no longer be counted upon, and arrangements were made for its production in England. Licences were issued by the Local Government Board to certain manufacturers suspending the patents protecting salvarsan and imposing a condition that every batch should be submitted to a biological test. The Medical Research Committee undertook to arrange for this testing as a war emergency, and it is on the experience gained during this testing of British and French products that much of this report is based. The story here unfolded reads like romance. The whole responsibility of testing these products was entrusted to one man, who laboured in the earlier months unaided, in inadequate premises, and with other work on his hands. There was but little information to go on, and knowledge could only be obtained by experience and careful observation. The supply of animals constituted an additional problem. Mice, which had been used at the Georg-Speyer Haus, were found to be in some ways unsuitable. As the arsenical preparations were to be used clinically as intravenous injections, it was felt that they should be tested biologically by the intravenous rather than by the hypodermic route, and to render this a practical proceeding rabbits were employed. It was then found that rabbits might in some instances show no signs of immediate poisoning, and yet give evidence of remote toxic effects, dying eventually of enteritis and renal necrosis. The proportion of British and French samples failing to pass this biological test grew at times so high as seriously to imperil the supply of material available for the country's need. Great discrimination was needed to steer a course between the perils of allowing toxic products to pass into use and of depriving the country of what it urgently required. That this was done, and done successfully, is due to the Medical Research Committee, and in particular to Dr. H. H. DALE who undertook this work in addition to his other labours. The achievement will be best understood by those who can appreciate the difficulty under which the work was done.

The testing of salvarsan and its substitutes has, however, a present as well as a past interest. The toxicity of these drugs is exceedingly high. They are also relatively costly. The temptation to dilute the toxicity of any sample by adding some inert and useless powder is considerable. Fraudulent substitutes without any arsenic and having no therapeutic value have already appeared in some countries. It is obvious that a strict control must be exercised over these preparations to prevent the advent of dangerous or useless samples. This control must be exercised by some Government Department, such as the Ministry of Health. Batches of salvarsan products will require to be submitted to biological testing, the tests being undertaken in a central Government laboratory or in laboratories provided by the various manufacturing firms, and approved of and inspected by Government. The Medical Research Committee is inclined to advocate the adoption of the second alternative, and to regard the scheme of decentralised testing as the more practicable. The onus of providing adequate arrangements for testing would thus be thrown on the manufacturer, the holder of a licence being required to submit records of careful testing whenever required. In the matter of imported products the same care must be exercised, entry being refused to all foreign preparations that have not undergone similar testing. Much useful knowledge has been gained as the result of the emergency measures adopted during the war, and the task of safeguarding the public from toxic or fraudulent preparations will have been rendered considerably easier by the work that the Medical Research Committee has so efficiently carried out. The preparation of adequate machinery for discharging these duties in the future is a task of no small importance.

◆

The Remuneration of Panel Practitioners: The Award.

Two months ago the Insurance Acts Committee, acting on behalf of the medical profession, and in accordance with instructions received from the Conference of Local Medical and Panel Committees, accepted arbitration upon the capitation figure which should be paid to medical men working under the National Insurance Act. The circumstances are well known to all our readers, and are, moreover, set out clearly in our columns this week by Dr. H. B. Brackenbury, the Chairman of the Insurance Acts Committee, whose facts seem to us not open to challenge, and whose deductions are made with an evident spirit of fairness.

The arbitrators, Mr. W. F. Gore-Browne, Sir R. Vassar-Smith, and Dr. J. C. Stamp, under their terms of reference, issued on Friday, March 5th, the following award:—

> We, the undersigned, having taken upon us the reference to us by the Ministry of Health and the Insurance Acts Committee of the British Medical Association, namely, "to advise the Government what should be the amount of the capitation fee (per insured person per annum) on the basis of which the Central Practitioners Fund, under Article 19 (i.) of the Medical Benefit Regulations, 1920, should be calculated so as to afford fair remuneration for the time and services required to be given by general practitioners under the conditions set out in those regulations, in connexion with the medical attendance and treatment of insured persons," taking note of the agreement that "the capitation fee is not to include any payment in respect of the supply of drugs and appliances (such payments being met out of the Drug Fund under Article 22), nor any payments to meet those special conditions of practice in rural and semi-rural areas, which are covered by the payments to be made out of the Central Mileage Fund, under Article 19 (ii.),"
>
> And having heard and considered the statements of fact and arguments submitted to us,
>
> Do hereby award, determine and advise that the capitation fee per insured person per annum defined as above should be eleven shillings.

The award is in general accordance with expectation; it forms rather less than a middle term between the demand of the medical profession and the sum which the Government was prepared to find. There will certainly be some disappointment, but, having regard to the fact that the terms are later open to variation, there should certainly be no overt manifestation of reluctance to abide by the pledges which are entered upon in accordance with the findings of the arbitrators. We trust sincerely that the early work of the Ministry of Health will not be prejudiced by any bickering, which would present a damaging picture of the spirit in which the medical profession as a whole is willing to undertake national work. The statement in the House of Commons by the Minister of Health that the award has been received on both sides with the utmost goodwill is reassuring.

To the last paragraph of Dr. Brackenbury's article we draw attention, particularly in view of his insistence upon the temporary nature of the settlement arrived at. Anticipating an early reopening of the remuneration question, as well as an unsympathetic reception of the medical views to be then expressed, he urges that the profession should place itself in a much stronger position with regard to unity of action and a defence fund. This is a sentiment which fully accords with the programme of the Federation of Medical and Allied Societies, which, given the necessary backing, should form a valuable link in negotiations between the State and the medical profession. It seems to us imperative in the best interests of medicine, and therefore of the public, that no idea should get abroad that medical men are working only for their own hand; and it might help the Government substantially to be supplied with the arguments, from a public point of view, why professional demands should be met in a more generous way than Dr. Brackenbury would seem to count upon. If the British Medical Association were to help the Federation to fulfil quickly what it has already made a good start upon, it would be surrendering, as far as we can see, nothing in influence or dignity, while coming into wider yet closer relations with those whom all medicine serves.

◆

Health Insurance Records.

The Minister of Health and the Scottish Board of Health have appointed an Inter-departmental Committee to consider and advise them as to the form of medical record to be prescribed under the conditions of service for medical practitioners contained in the new Medical Benefit Regulations, having due regard to the clinical as well as administrative and statistical purposes which such records will serve. The Committee, whose personnel is set out elsewhere, will be presided over by Sir Humphry Rolleston, and includes Mr. R. W. Harris, assistant secretary of the Ministry of Health; the Superintendents of Statistics at the General Register and the Edinburgh Register Offices; the Director of Statistics of the Medical Research Committee; the Chairman of the Insurance Acts Committee, and the Director of Medical Services at the Ministry of Pensions. Dr. G. F. McCleary and Mr. A. E. Joll will act as joint secretaries.

Annotations.

"Ne quid nimis."

UNIVERSITY OF LONDON O.T.C. MEMORIAL FUND.

AN appeal is being issued by a strong committee for funds to establish a war memorial for the University of London Officers' Training Corps. Major B. M. Cloutman and Brevet Major A. C. T. White, the honorary secretaries, are the two survivors of the five former members of the contingent who gained the V.C. during the war, the other three being Captain John Fox-Russell, R.A.M.C., Major Frederick Henry Johnson, R.E., and Captain Allastair Malcolm Cluny McReady-Diarmid, Middlesex Regiment. A standing camp for the contingent has been acquired at Great Kimble, Bucks, and the suggestion is to perpetuate the memory of former members killed in the war by the erection of a permanent hall on this site, as well as by a memorial in London. The nature of this memorial is not yet settled, but presumably it will take the form of a tablet in some suitable place, so that most of the money subscribed can be allocated to the proposed hall. The number of past and present officers and cadets of the University of London O.T.C. who served as officers in the war is 4197, and of these 657 are known to have fallen. They served on every front, and assisted in the defence of London, one of them bringing down a Zeppelin near the City and later a Gotha aeroplane. They gained in all 1650 distinctions. It is proposed to dedicate a personal memorial to Lieutenant-Colonel Arthur Egerton, Coldstream Guards, first Adjutant of the University of London O.T.C., who fell in action near Loos, and proposals for other special memorials at the standing camp to individuals or groups will be sympathetically considered. It is hoped to raise £30,000 for the whole scheme. Contributions to the fund should be remitted to the honorary treasurer at 46, Russell-square, London, W.C. 1.

MODIFIED ENTERIC IN INOCULATED PERSONS.

IT is now generally agreed that enteric fever occurring in a patient who has been inoculated against the disease is altogether of a milder order than the same disease in an uninoculated person. This fact was constantly observed by R.A.M.C. officers who had the opportunity of studying cases of enteric among the unprotected civilian population of France and among our protected troops. The disease may be so mild indeed as to lead experienced clinicians astray. The difficulty of diagnosing typhoid and paratyphoid infections, among the very large numbers of cases of pyrexia of doubtful origin, was therefore constantly present and exercised the wits of clinician and bacteriologist alike. In the end bacteriological diagnosis was the final court of appeal. Where either a typhoid or paratyphoid bacillus could be isolated from the blood or from the stools, there was, of course, no hesitation in classing a case as enteric, however mild the symptoms may have been. But the exigencies of military service often prevented the prolonged observation of a patient in the early period of his disease, and bacteriologists were consequently unable in a large number of cases to give a definite opinion as to the nature of the disease. It was in such cases as these that the diagnosis of enteric by fluctuations in the agglutinating power of the serum was most practised. The reliability of the method, which we owe to Professor G. Dreyer and his co-workers, has been, and still is, keenly debated. Those who accept the method without reservation are led by their results to believe that a considerable proportion of cases of P.U.O. were in reality cases of modified enteric; and they are further compelled to conclude that prophylactic inoculation not only reduces the incidence of the disease and moderates its severity, but that it also diminishes the chances of recovering the infecting organism from the blood or fæces or urine. The debate on this important subject is not yet ended, but an informing contribution to the discussion has been made in a Green Book just published by the Medical Research Committee.[1] In this essay Drs. W. W. C. Topley, S. G. Platts, and C. G. Imrie review the whole question in an impartial way. They have investigated in an experimental fashion the basis of Professor Dreyer's method, which they conclude is trustworthy and enables "successive determinations of the agglutination titre of the serum to be carried out with the requisite degree of accuracy." They discard, however, the method of recording the agglutinin in terms of "agglutinin units," a reservation of considerable importance. By means of the Dreyer technique Dr. Topley and his collaborators have studied atypical febrile conditions, and have arrived at the conclusion that some 5 to 7 per cent. of the cases of P.U.O. from the Western front were enteric of one sort or another. In giving this result the authors frankly recognise that its validity depends entirely upon serological evidence, and "must stand or fall by the reliability of this method of diagnosis." They admit fully the importance of the criticisms and conclusions of the American Trench Fever Commission, which subjected the method to a thorough and searching test and finally declared that fluctuations of agglutinin titre are of no diagnostic significance. But upon the balance of evidence they are inclined to believe that their own conclusions are valid.

A CONTRIBUTION TO THE CHEMISTRY OF VITAMINES.

AN interesting paper on "The Preparation of a Stable Vitamine Product and its Value in Nutrition," read before the Division of Biological Chemistry at the Fall meeting of the American Chemical Society, Philadelphia, appears in the February number of the *American Journal of the Medical Sciences.* The authors, H. E. Dubin, Ph.D., and M. J. Lewi, M.D., prepared a vitamine product "V" from corn, autolysed yeast, and orange-juice materials which assured the presence of all three vitamines—antineuritic, antirachitic, and antiscorbutic. The combined materials or extracts were dried in vacuo at 40° C., a temperature which leaves the accessory factors unimpaired. A tentative analysis of the product obtained showed the following chief constituents: Calcium (CaO), 10 per cent.; phosphorus, 15 per cent.; nitrogen, 3·5 per cent.; fat, 2·5 per cent.; iron, 0·3 per cent.; silicates, 5·6 per cent.; moisture, 10 per cent., the remainder being made up of the rest of the phytin molecule —of which, according to these authors, the vitamine preparation is chiefly constituted—which is a double calcium and magnesium salt of inosite pentaphosphoric acid. The results of the experiments with normal and polyneuritic pigeons, normal and scorbutic guinea-pigs, and, more important still, with children presenting evidence of malnutrition, marasmus, and rickets, showed a marked acceleration in the rate of growth, particularly in the case of children. It seems established that all three vitamines were present in the preparation, and the authors attach importance to the calcium and phosphorus in the product, which they regard as having a beneficial action on the general metabolism, more particularly on bone and tooth formation. They assert that until such time as the vitamines shall have been isolated, and their chemical composition determined, the vitamine preparation which they have produced may be trusted to be effective as an accessory food factor. The investigation is being continued with the hope of isolating and determining the chemical composition of the vitamines. The chemist so far has found these entities elusive, but their importance should stimulate the hunt.

---

[1] Medical Research Committee: Special Report Series, No. 48. A Report on the Probable Proportion of Enteric Infections among Undiagnosed Febrile Cases Invalided from the Western Front since October, 1916, by Drs. W. W. C. Topley, S. G. Platts, and C. G. Imrie.

SUPRAPUBIC HÆMATOMA OF THE RECTUS MUSCLE.

IN the *Progrès Médical* of Jan. 18th, Dr. F. Cathelin has described an interesting injury which comes under the observation of French army surgeons—suprapubic hæmatoma of the rectus muscle in young horsemen. It is always produced in the same manner, but the diagnosis would be very difficult for a clinician whose attention had not been directed to the injury by a previous case. While director of the Urological Centre for the Fifth Region during the war, Dr. Cathelin had eight cases sent to him in a few months. The following are examples:—

A young cavalryman, while mounting his horse from the left side, felt a slight suprapubic pain which did not prevent him from continuing on duty on that and the following days. The pain reappeared on mounting, but did not continue when in the saddle. A hard, smooth, regular, painless swelling was found in the subumbilical half of the right rectus muscle. The swelling ceased sharply two fingers' breadth below the umbilicus, and at the lower end was lost in the pubic bone. The left rectus showed nothing abnormal. Recovery took place in a fortnight under rest in bed and hot fomentations. In another case a man felt a violent pain in the lower abdomen on mounting. He was able to continue a riding lesson, but suffered much during trotting and jumping. On the following day he was able to mount without pain, but in the evening, on vaulting, he felt a violent pain, which immobilised him. He maintained a stooping posture and could not straighten himself. On examination acute pain was felt on palpation and on the slightest movement at the external border of the left rectus muscle, extending from the pubic bone to five fingers' breadth below the umbilicus. On palpation puffiness and a hard and painful swelling of the size of a small orange was felt beneath the muscle. The swelling disappeared under the same treatment and in the same time as in the previous case.

In all the cases the ætiology was the same. The patients were young soldiers of the classes 16 and 17 in the first months of cavalry training. In jumping or vaulting they felt, on widely separating the legs, a slight pain in the lower abdomen, which sometimes prevented them from continuing the exercises. Usually there was no pain on palpation. The swelling was sometimes circumscribed, at other times diffuse, smooth, regular, and always unilateral. Its position beneath the muscle gave a sensation of depth. It was always at the lower part of the rectus, generally on the left side. In spite of its suprapubic position vesical signs were always absent. The pathogenesis is explained by the fact that the aponeurosis surrounding the recti is absent posteriorly over the lower third where there is only a thin cellular layer, between which and the muscle run the epigastric vessels. The production of the hæmatoma has been attributed to several mechanisms: 1. Repeated impact of the abdominal wall against the pommel of the saddle in jumping on a horse without stirrups, which produces small muscular ruptures, the origin of a more important rupture during horse exercise. 2. Muscular rupture, such as occurs in sprain of the back or rupture of the tendo Achillis. Against this view is the almost complete absence of pain. 3. A tearing away of bone from the pubis at the attachment of the rectus. Again the absence of pain is against this view; so is the absence of ecchymosis. 4. The most probable hypothesis seems to be rupture of branches of the epigastric artery. It is well known how easily these branches are ruptured when the muscular fibres are separated to enlarge the incision for lateral laparotomy.

A NAVAL OFFICER ON CONDITIONS IN MERCHANT SHIPS.

EFFORTS were being made for some time before the war to improve living conditions for the crews of merchant ships. The Board of Trade was interested, its medical officers certainly were, and it was believed that ship-owners were to some extent conscious that their crews, including the stokers who fed the furnaces, wanted, and were entitled to, something better in the way of sanitation, including sleeping and feeding accommodation, than had been given them in the past. If anyone desires to see how the living accommodation for the firemen of a good-sized liner, in use as such in 1914, appeared to the eyes and other senses of an experienced officer in H.M. navy he will find full particulars in the closing chapter of a series of interesting articles in *Blackwood's Magazine* for February, 1920. The writer, Rear Admiral Boyle Somerville, describes the work of the Ninth Cruiser Squadron, with particular reference to a liner converted into a cruiser. What that work was, so far as the war was concerned, can be read in the articles referred to. With regard to the matter of the ship's equipment, as studied by the writer in connexion with the process of conversion, Admiral Somerville found much to disapprove of, but the "first and worst and rudest shock of all" came when he went the rounds of the living quarters allotted to the deck-hands and firemen of the ship's original crew in the routine of the first Sunday morning at sea. The quarters of a man-of-war's crew, as he observes, are not laid out in over-luxurious fashion. What he found in the way of darkness, lack of ventilation and sanitation, filth, and vermin in the forecastle and the depths beneath it in his new command is told with breezy candour and with full particulars of the remedial steps immediately taken, including the washing out and sealing of the part of the ship previously used for sleeping in, and the throwing overboard of the abominations provided for bedding. After that decks, dismantled of the woodwork compartments which once had been cabins, but still equipped with baths, became the crew's living places. The effect of what was done in producing contented and orderly service, as well as the results of training under efficient stokers in the saving of coal, might usefully be considered by ship-owners and legislators interested in our seamen. Admiral Somerville's point, put shortly, is that training and decent treatment for firemen would pay for any immediate outlay involved, and that those who give conditions which only the dregs of the male population will accept only get that class to serve in their ships, to their own loss as well as to their discredit.

DENTAL CHANCRE.

OWING to the rarity nowadays of syphilitic infection arising from the use of unsterilised dental instruments, a case reported by Dr. Herman Goodman,[1] of New York, is of interest. The patient was an American officer, 32 years of age, who was married and had two healthy children. Ten to 14 days after extraction of a tooth by a civilian dentist an ulcer appeared at the site of the extraction. A Wassermann reaction taken at the time proved negative. The ulcer healed under local treatment, but recurred. About six weeks later there was a generalisation of the syphilitic infection, which was shown by inflammation of the jaws and ulceration about the right molars, bilateral swelling of the submaxillary glands, pharyngitis, and a positive Wassermann reaction. There were no lesions on the genitals. After three doses of arsenobenzol the symptoms disappeared and the Wassermann reaction became negative.

THE GENESIS OF THE MAUDSLEY HOSPITAL.

THE institution by the London County Council of a course of lectures and practical instruction at the Maudsley Neurological Hospital, in preparation for the Cambridge Diploma of Psychological Medicine, leads us to recall the initial impetus given to the scheme by Sir Frederick Mott. In the *Archives of Neurology* for 1907, writing of post-graduate teaching in medico-psychology and neuro-pathology, he said :—

> A fruitful field of study in psychiatry would be those early cases of uncertifiable mental affection termed neurasthenia, psychasthenia, obsession, mild impulsive mania, melancholia, hysteria, and hypochondria, which in many instances are really the prodromal stages of a pronounced and permanent mental disorder. The poorer patients suffering with these conditions first come into the hands of the practitioner, the dispensary or infirmary doctor, and the out-patient physician at the general or special hospitals. The better class patients are sent by the practitioner to the neurologist; the generality of the poorer patients, and sometimes the better class patients, are regarded by the medical man who has had no training in psychology as of little medical interest (for such patients do not, as a rule, benefit by drugs), and he finds it a wearisome task to listen to their story, to ascertain their inborn tendencies, and to find out the truth of what has happened to account for their strange conduct indicative of their not feeling, thinking, and acting in accordance with the general usages of their social surroundings, and yet such patient may not be so anti-social as to be certifiable. Such cases are often in the hopeful and curable stage, and these, if studied carefully by trained medico-psychologists, could not fail to yield valuable results in regard to our knowledge of the causation, prevention, and cure of insanity. Moreover, when the cases are followed up systematically they would throw much light on prognosis in similar cases. The majority of cases which are admitted to the asylum have long passed the hopeful stage; still, there are a certain number of early curable cases, and these, I maintain, would sometimes be much better if they had not been certified or sent to associate with chronic lunatics. Fortunate would be the community in which there was a fully equipped and well-organised psychiatrical clinic, under the control of a university, and dedicated to the solution of such problems.
>
> The scheme of the London County Council for Receiving Houses would probably include the establishment of an acute hospital for the investigation and treatment of curable mental cases, to which a clinic might with advantage be attached. Hereby post-graduate teaching would be encouraged, and the better knowledge and early treatment of insanity would certainly prove of great economic advantage. If suitable post-graduate training in medico-psychology and neuro-pathology were established, doubtless the universities and licensing bodies might be induced to establish a diploma, very much on the lines of the Diploma of Public Health, which has largely contributed to raise the science of public health to the high position it now holds, thus conferring an inestimable benefit on the nation.

The offer by Dr. Henry Maudsley of £30,000 to further precisely these aims was made to the Council on Feb. 18th, 1908, and there is no reason to doubt that Sir Frederick Mott's statement largely induced Dr. Maudsley to make his munificent offer.

POST-ANÆSTHETIC TOXÆMIA.

A RECENT inquest has directed attention once again to the obscure condition known as post-anæsthetic toxæmia, or, as it has been less precisely termed, "delayed chloroform poisoning." Chloroform is, we know, not the only, although it is the most usual, anæsthetic associated with these cases of persistent vomiting, restlessness, delirium, coma, and death. It was in the columns of THE LANCET in 1894 that the late Dr. Leonard Guthrie first directed attention in this country to a condition which had already been described on one or two occasions on the continent. Dr. Guthrie's description remains the best clinical picture of the symptoms exhibited by patients who suffer from post-anæsthetic toxæmia, nor has much knowledge been added to that which he gave us upon the post-mortem appearances in these cases. The association of acidosis with this condition had, however, not yet been recognised, and treatment, therefore, had not yet been designed, as it now has been, based upon the assumption that the symptoms are due to the faulty products of metabolism present in an organism that is suffering from acetonæmia or the state immediately precedent to this. Whether this supposition is correct or not, the use of glucose prior to operation, and bicarbonate if symptoms develop after, seems to have good clinical justification. The feature about this condition, which makes any explanation of it dependent upon the anæsthetic so difficult of comprehension, is the fact that in many instances the anæsthetic has been of extremely short duration, and in some the drug employed has been one of far less toxic power than chloroform. In the case recently recorded the operation lasted only a quarter of an hour, and was one that involved no hæmorrhage at all, being a manipulative procedure. Yet the post-mortem appearances were well marked and included the characteristic fatty infiltration of the liver described by Dr. Guthrie. It was the presence of this condition in patients who had succumbed within a day or two of operation that led Dr. Guthrie to suppose that a pre-existing faulty state of the liver must be present. The histological changes were, he thought, too extensive and advanced to have been produced within the short time intervening between anæsthesia and death unless they had already begun beforehand. The importance of discovering in the urine of patients before operation the presence of alkaloidal bodies is that these indicate faulty liver metabolism. Thus more recent investigations link up with Dr. Guthrie's original hypothesis of pre-existing liver disturbance in patients who become the subjects of post-anæsthetic toxæmia.

HEALTH OF THE U.S. ARMY IN 1918.

In a recent number of the *Military Surgeon* Major Soper deals with the sickness occurring in the U.S. army during 1918, based upon the weekly reports from stations to the central office. The figures are obviously not final, but their small inaccuracies are far more than compensated by the promptitude with which the broad lines of disease prevalence are made publicly available. During 1918 the army increased from 217,272 to 1,538,293 men, and as the recruits joined the cases of infectious diseases mounted up. All comparisons with previous years were upset by the influenza epidemic, which seems to have commenced in March in the south-east, to have progressed slightly during the summer, but to have taken on a virulent infectiousness only in autumn. Pneumonia caused most deaths (24,538), influenza is only discredited with 1133, but the most deadly disease was cerebrospinal fever (883), 42 per cent. More days were lost from measles than from any other disease; next come gonorrhœa and mumps. Troop movements carried infections, and the respiratory infections spread more widely and were more fatal in barracks than in camps. The camps had much higher death-rates than the large cities of the United States. Recruits are susceptible to disease, especially when they first arrive and have not learned how to take care of themselves; but to the end of their training, when they are doing more and more work, they are very likely to get worn out. The Americans in France suffered fewer attacks of illness than those at home, and were less apt to die, but in France bronchitis, influenza, mumps, scarlet fever, and dysentery were more prevalent and fatal than in the United States. Influenza in the United States attacked 57·72 per 1000, and 0·01 died, but in France the figures were 101·16 and 0·04. Colonel Lynch and Lieutenant-Colonel J. G. Cumming insist that mess gear of troops shall be boiled after each meal to prevent the conveyance of infection from mouth to mouth by cups and forks. Of 160,000 troops returning from France in 68 ships, 97,000 had their mess gear boiled, 62,000 only their mess gear washed in warm water. These last had more respiratory infectious disease, and, in particular, had three times as many cases of influenza and of pneumonia. (If spoon boiling is the secret of avoiding infection, why had the camps mentioned above less respiratory disease than the barracks where dish washing was probably better done?) Account is given of 500 cases of scarlet fever which occurred in a camp in Georgia. Here the important observations seem to be that in many cases the rash is transient and inconspicuous, perhaps even it may be absent, the disease slight, and attention only called to the condition when desquamation begins. On the second day there develops a polymorphonuclear hyperleucocytosis and a general enlargement of the glands. So that if a suspicious case has on the second day a bilateral enlargement of the inguinal glands it should be diagnosed as scarlet fever. On the third day a characteristic eosinophilia (2 to 5 per cent.) begins to develop and the more marked as the case is more serious. In respect of diphtheria in the American Expeditionary Force, the most effective measure of prevention was the immunising of susceptible men, but the disease gave endless work to the central and divisional laboratories.

GAS CYSTS OF THE INTESTINE.

ACCORDING to Dr. M. D. Stoyanovitch,[1] who devotes his thesis to the subject, this rare condition was first described by Duvernoy in 1754, and since then only about 50 cases have been recorded. The cysts, which vary in size from that of a grape-seed to a grain of wheat, are found massed together like a bunch of grapes. Their favourite situation is the small intestine, but they have been found on the parietal and diaphragmatic peritoneum, the meso-colon, omentum, and intestinal adhesions. Histologically they are situated in the submucous and subserous coats, and exceptionally in the muscular wall of the intestine. They are grouped round the lymphatics, and are remarkable for their vascularity. The condition, which has been found between the ages of 13 and 67, may occur by itself, but, as a rule, is associated with another disease, such as stenosis of the pylorus due to gastric ulcer, tuberculous peritonitis, or appendicitis. The symptoms are vague, and the cysts are often found unexpectedly at an operation undertaken to relieve the concomitant affection. The physical signs are distension of the abdomen or resistance in the epigastric region, with gastric splashing or a tympanitic note. Valuable information is obtained by radioscopy, which shows the presence of clear zones. The complications which may occur are pyloric or intestinal obstruction. Various theories have been advanced to explain the formation of the cysts. The mechanical theory that they are due to the passage of the intestinal gas into the subserous tissue is contradicted by the nature of the gas, which resembles that of atmospheric air, and by the localisation of the cysts in other situations than the intestine. The theory that they are tumours formed at the expense of the lymphatics fails to explain the presence of gas. The microbial theory, which appears to be the most probable, is supported by Dupraz, who isolated a liquefying coccus which on injection into a bitch reproduced the cysts in the vagina. As regards treatment, if the cysts are merely discovered in the course of an operation for some other abdominal affection they need not be removed. If they give rise to pyloric obstruction, gastro-entero-anastomosis will be required. In the case of intestinal compression, or obstruction of the lumen by the cysts, entero-anastomosis or resection of the affected loop should be performed.

MATERNAL AND CHILD WELFARE UNDER THE LATE LOCAL GOVERNMENT BOARD.

Section 12 of the Medical Supplement to the 48th (and last) annual report of the Local Government Board is from the pen of Dr. S. W. Wheaton, and deals with maternal and child welfare during 1918–19. Although of great interest as a record, it reads like ancient history in view of the rapid progress since achieved in the face of difficulties.

---

[1] Thèses de Paris, 1918-19, No. 230.

The supplement states that on the cessation of war conditions it was hoped that a large army of workers would be set free to resume their efforts for the reduction of maternal and child mortality; but, unfortunately, the prevalence of influenza interfered with this work. The health visitors, nurses, and other workers who were not retained by the needs of the navy and army were to a large extent employed in the visiting and nursing of sufferers from influenza, with the result that the maternity and infant welfare centres over large areas had to be closed for a time, while maternity homes and other institutions were gravely affected by the incidence of the epidemic on the staffs and inmates. At the same time, the existence of a trained welfare staff provided local authorities with a reliable force, which must have been of the first importance in reducing mortality from influenza. The further use of this staff in case of epidemics of measles, whooping-cough, or diarrhœa and enteritis is an obvious corollary of its success in influenza. The absence of rise of infant mortality in the year 1918, in spite of the adverse conditions of war and influenza, while a matter for congratulation, is attributed by Dr. Wheaton to the presence of climatic conditions favourable to infant life, the mortality being low in regard to the infectious diseases especially dangerous to infant life. The year was a mild and wet one, the winter months being unusually warm and the summer months correspondingly cool; rainfall was heavy, 4½ in. above the average, and unusually plentiful in the months of highest temperature. Various philanthropic agencies and welfare organisations have claimed the share in the reduction of infantile mortality in 1918 which the report ascribes to the gentle influence of the elements, and we can only trust that their continued activity may show favourable figures under more rigorous conditions. The opportunity is there, for, according to the directory,[1] which has just reached us, there are now 1718 maternity and child welfare centres in England and Wales, of which 331 are conducted by county councils, 708 by local sanitary authorities, and 679 by voluntary societies. In London nearly 80 per cent. of the centres are still under voluntary direction.

SLEEPING SICKNESSES.

IN 1734 John Atkins described, under the term "sleeping distemper," a disease which he found to be common among the natives of the "coast of Guiney," and, although it was not until 1903 that the work of Castellani, Bruce, and others linked up the disease with a particular stinging fly and a characteristic blood parasite, the term "sleeping sickness" has been in general use for nigh on two centuries to denote this form of negro lethargy. Since 1903 "sleeping sickness" has become synonymous in medical literature with trypanosomiasis, and Castellani and Chalmers head the relevant chapter, in the recent edition of their Manual of Tropical Medicine "sleeping sicknesses." A similar nomenclature is in use the world over; we need only mention (Fr.) maladie du sommeil, (Ital.) malattia del sonno, (Ger.) Schlafkrankheit, (Port.) doença de sômno. It would, therefore, be very inconvenient and lead to needless confusion if the same term is used for quite another malady, as there is a tendency to do in the daily press at the moment. The little epidemic of encephalitis occurring in England during the spring of 1918 was unfortunately labelled "botulism" for a while and a gamut of other terms, such as toxic ophthalmoplegia and Heine-Medin disease, was employed until at the combined sections of the Royal Society of Medicine in November, 1918, it was agreed to follow von Economo in the use of the word "encephalitis lethargica." It was at this discussion that Professor A. J. Hall suggested that "sleeping sickness" would not be an inappropriate name for the epidemic, and the lay press has taken his view and acted upon it. It remains for those who are concerned for an informed and accurate public opinion on health matters to devise some popular term for encephalitis lethargica less cumbrous than "lethargic encephalitis" and free from the objection to "sleeping sickness." The disease is too new to appear at all in the official Nomenclature of Diseases (5th edition, 1918), which gives no help in the matter. It might be well to revive "nona," which was the term used to describe a similar outbreak of febrile illness with somnolence in Italy, Bavaria, and Russia, in the year 1890. The word has the merit of never having been used to describe anything else and of not committing the user to any theory of causation, the actual agent of the disease being still as uncertain as the derivation of the word.

THE SALARIES OF ASSISTANT MEDICAL OFFICERS.

THE recommendations made at different times by the British Medical Association with regard to the salaries of medical men employed by Health Authorities have contained, with their excellent intentions, more than one anomaly. This has embarrassed alike Authorities in offering conditions of remuneration, candidates in applying for vacancies, and medical journals in accepting advertisements. In respect to the last, we have decided not to accept advertisements in these columns for the future where the pay offered for assistant medical officers is less than £500 per annum or its equivalent.

Sir George Makins has succeeded the late Sir William Osler as President of the Fellowship of Medicine.

"IN 1917 for every 10,000 births 48 mothers died" is the form in which the statement should have been put in our leading article of Feb. 28th entitled "Safety and Comfort in Child-Bed," as several correspondents write to point out. We regret the obvious slip.

THE fifth congress of the Société Internationale de Chirurgie, of which the general secretary is Mr. L. Mayer, rue de la loi 72, Bruxelles, will be held in Paris from July 19th to 23rd, to be followed by a week's tour of the French and Belgian battlefields. Members are asked to inform the secretary as soon as possible whether they intend to be present. A detailed programme of the congress, from which representatives of Central Europe are to be excluded, will be issued shortly. A provisional list of subjects includes surgery of the cardiovascular system, destructive radiology, surgical hæmatology, fractures of the femur, and the prophylactic and curative treatment of tetanus.

SOME THOUGHTS ON THE ARBITRATION.

BY H. B. BRACKENBURY, M.R.C.S.,
CHAIRMAN OF THE INSURANCE ACTS COMMITTEE.

WHEN the Insurance Acts Committee, on behalf of the profession and in pursuance of the instructions of the Conference of Local Medical and Panel Committees, suggested arbitration with regard to the capitation fee for insurance practitioners, an undertaking was of course given on both sides that the award of the arbitrators would be loyally accepted. The Government is now pledged to use every effort to get the House of Commons to pass Estimates which will provide the money required; the Committee is pledged not to promote any organised effort to refuse service; and insurance practitioners are pledged to do their work honestly under the conditions of the award. These pledges are, however, not unlimited as to duration; it is understood that after the year 1920 a notice of not less than three months may be given to vary the terms and conditions of service, to alter the basis of remuneration, or to repudiate service altogether by organised effort.

Moreover, a loyal adherence to the terms of the award on this understanding does not mean that the award is accepted as being either just or satisfactory. To those who know the course of events when the Government was considering its reply to the demand of the profession for a capitation fee of 13*s.* 6*d.*, and the pressure from various quarters which was then being brought to bear on the Ministry of Health to resist any payment of more than 9*s.* or 10*s.* as an extreme limit, the extraction of the offer of 11*s.* from the Government appears something of an achievement. To have accepted this offer, however, at that stage might reasonably have been held to be an admission of its fairness and adequacy. To submit to the same basis of remuneration now at the hands of the arbitrators involves no such admission; it leaves the profession free to maintain its opinion that under present conditions no capitation fee of less than 13*s.* 6*d.*—or from that sum up to about 15*s.*—is fair or adequate for the kind of service which it had in contemplation, and free to take at the proper time any legitimate action that it thinks fit to carry that opinion into practical effect. Personally I am prepared to maintain this standpoint as strongly as ever.

A Missed Opportunity.

To many of us the main disappointment in the matter is that the Government has missed a magnificent opportunity—one which is not likely to recur, at any rate in so favourable a form. At the present stage of national health developments the fundamental necessity has appeared to us to be the definition, the establishment, the encouragement of a "general practitioner service" (not with reference to the Insurance Acts only) of the best type, and with the widest outlook as regards its responsibilities towards both the individual and the community. In the case which the Insurance Acts Committee submitted to the arbitrators the outline of such a service is made quite clear, and the provision of such a service is offered. In the observations made on behalf of the Government—both printed and verbal—presented to the arbitrators, though some pen-service and lip-service is paid to the idea, there is a repudiation of this as a practical thing, and a belittlement of what is at present required or immediately contemplated. It has been understood by those representing the profession throughout all these discussions that the main object of the revision was to improve the present service and to provide one of a comprehensive kind which would expand and fit in with additional medical and accessory services. Yet we find the Government saying that "the number of doctors willing to undertake service on the terms offered was ample to provide a sufficient service in every part of the country, and that service has remained adequate, in respect of numbers, throughout." It is notorious that there are areas in which the inadequate number of doctors is the chief cause of some serious deficiencies in the kind of service rendered, yet the Government is satisfied with this. Again it is said "the number of doctors necessary is so large that it would be impossible to confine choice to the best," and "a relatively high rate of remuneration will not alter the professional capacity." Obviously, however, the capacity *of the service* is materially altered according to the number of individuals of higher or lower professional capacity who are attracted to it or retained in it, yet the Government appeals for an award of such remuneration only as will ignore this. Again, the Government states that the profession's estimate is based on "an ideal standard of service," that a "high ideal type" is "visionary," that it cannot afford to pay for "potentialities of service that are not likely to become realities within the immediate future," that "considerations advanced as regards public health and research are not relevant," that "no obligation arises under the regulations" with regard to some professional work and responsibilities and, "there being no obligation," there can arise no question of remuneration in respect thereof. All this was not to be expected of the Ministry of Health or even of an intelligent Treasury; and it is profoundly disappointing to discover that at a time when a new era of health administration is supposed to be beginning, and when within the profession there is a spirit of eagerness to offer every service that can properly be asked from them, the Government should base its case on a repudiation of the conception put forward on the part of the profession, and should ask for an award on the assumption that these services are not required, or should not be encouraged, or would not be forthcoming. We must accept the lower level of service as what it is now proposed to pay for; we shall no doubt give good and honest value on that level; but once more it is proved that the profession is willing to give practical effect to ideals far in advance of those held by politicians and administrators—even those who are specifically charged with the care of the public health.

On such a level as that indicated it is possible to hold that a capitation fee of 11*s.* affords a fair basis for a minimum remuneration. The Insurance Acts Committee maintains that even on this level it is not enough. The reference to the arbitrators was so framed that they could discharge it by the mere mention of a figure as their award. This is what they have done, and it is therefore impossible to be sure how this figure was arrived at. To those of us, however, who through nearly eight hours were trying to follow the minds of the arbitrators, it seems not improbable that the final stage of the conclusion was something like this: "We will assume that 2*s.* 6*d.* out of any capitation fee is required for expenses. We will assume that a general practitioner can properly attend to 3000 persons (not necessarily insured persons) in a 2400 hour-year. A net fee of 8*s.* 6*d.* will therefore produce an income at the rate of £1275 net. This is approximately what both sides have said is not unreasonable for a general practitioner as such, working his ordinary full time." This is a supposition, but, in fact, the result may correctly be stated in that way.

What the Negotiators have Accomplished.

Those who have conducted the negotiations on behalf of the profession have therefore accomplished this—that, on the new basis of remuneration, a practitioner who claims that he is able properly to attend to 3000 persons in all will be paid in respect of those who are insured persons at the rate of £1275 a year net, while he will be at liberty to cultivate any professional work of a more special character and to charge fees therefor at a higher rate, or to attend, if he can, a larger number of patients by working longer hours than those regarded as the normal. This is a very definite improvement on the existing state of affairs; to some members of the profession, and doubtless to many outside it, such remuneration will not appear unfair or inadequate for the kind of service postulated. If the profession determine—as I think it should—that this remuneration is still inadequate, it ought to show either: (*a*) that £1275 per annum is less than the proper value of a good general practitioner, or (*b*) that a higher sum than 2*s.* 6*d.* per person can properly be allocated to professional expenses, or (*c*) that the circumstances of the case or the capacity of a general practitioner do not permit of as many as 3000 individuals, *on the average*, being properly cared for, or (*d*) that the conception of a "general practitioner service" ought to be so enlarged as to necessitate a smaller number of persons being under the care of each practitioner without reduction of total income. Personally, I am prepared to maintain that every one of these propositions is true, and I fancy that nearly all practitioners will agree with this, with these exceptions—that some members of the profession who are not general practitioners may dispute the first, and that many general practitioners are still apt to deceive themselves about the third. We still need some clear thinking on this point, and I propose to conduct an inquiry as to the number of persons for whose health the State may properly require a general practitioner of ordinary competence and skill to be responsible, and I hope to put the result of such inquiry before the profession for discussion. In any case, it is clear that, in order to secure a further revision of remuneration in the early future, it will be necessary on all the above points to obtain a large amount of statistical information from practitioners. The absence of this was our chief weakness before the arbitrators, and this lack was not the fault of the Insurance Acts Committee or its officers, who have appealed over and over again to the profession to produce such statistics. May we appeal once more, now that the need is demonstrated, for the immediate and careful keeping of the records and figures needed?

Support of the Profession Required.

Experience teaches one thing more. If we are at the earliest possible time once more to raise the question, and to show once more, as we think, the complete reasonableness of our demands, should these demands once more be rejected by a short-sighted administration, the profession must be in a much stronger position with regard to unity of action and with regard to a Defence Fund than is now the case if action is to be effective. The present result is in many respects good; we had a right to expect it to be better. The machinery for negotiation has not proved to be at fault. The personnel is, at any rate, representative and very hard-working. But we shall never arrive at the full results we want to accomplish without the entire support, both moral and financial, of the whole profession.

VENEREAL RESEARCH IN U.S.A.:

WORK OF THE SOCIAL HYGIENE BOARD.

In a very exhaustive paper presented to the American Association for the Advancement of Science at St. Louis (Mo.) on Jan. 2nd Dr. William F. Snow and Dr. Thomas A. Storey deal broadly with the subject of Experimental Medicine and Venereal Diseases. The account is specially noteworthy for the epitome which is given of the scientific investigations now being carried on in America with the assistance of the United States Interdepartmental Social Hygiene Board. The summary is brought up to Jan. 1st, 1920, and is as follows:—

Cornell.—Dr. John C. Torrey is making a serological study of the gonococcus group in the Laboratory of Hygiene of the Cornell Medical School. This research is an investigation into the relationship of many strains of gonococcus from various sources to determine whether the group is homogeneous or heterogeneous. If the former is the case the research may establish a few groups of fixed types which will embrace the great majority of strains encountered in pathological conditions, as has been done for the pneumococcus and the meningococcus groups. Such a group would go a long way to establish the complement-fixation test for gonococcic infection on a more rational and satisfactory basis. If this research succeeds in establishing a standard antigen, we may not only expect that the complement-fixation mode of diagnosis will give more trustworthy results, but we shall have the basis for the preparation of a standard stock vaccine.

Harvard.—In the Pharmacological Laboratory at Harvard University investigation is being made by Dr. Reed Hunt relative to the toxicity of arsphenamine, neoarsphenamine, and analogous products.

Jefferson.—A search for a more rapid and specific method of demonstrating the *Treponema pallidum*, and for a simplification of the clinical diagnosis and treatment of syphilis, was carried out last summer by Dr. Randall C. Rosenberger and his assistants in the Laboratory of Hygiene and Bacteriology in the McFadden Laboratory of Research at the Jefferson Medical College. Results of these investigations should appear shortly.

Johns Hopkins.—Four groups of researches are being carried out in the Clinical, Pathological, Bacteriological, and Animal Experimental Laboratory of the Brady Urological Institute, Johns Hopkins University, under the direction of Dr. Hugh Young. With Dr. Young, Dr. E. C. White is working on the development of new synthetic drugs for the treatment of gonorrhœa. The drugs in present use in the treatment of acute gonorrhœa are, in the main, ineffective. There is great need of a more successful antiseptic. Clinical application of certain new drugs have given better results, and a promising new field for experimentation has been opened. This investigation is for the purpose of synthesising drugs which will possess qualities superior to those of the drugs in present use, and to test their comparative antiseptic values experimentally and clinically. Under Dr. D. M. Davis, working with Dr. Young, a research is being conducted for the manufacture and investigation of a series of new organic compounds for the treatment of syphilis. Salvarsan is now considered to have failed in producing radical cures of syphilis, and mercury is again being used to complete "cures." But great difficulties still exist in using mercury owing to the frequency of toxic results, especially on the kidneys. Some of the recent work in the Brady Urological Laboratory points to the possibility of employing new mercurial compounds which will be tolerated in larger quantities than the old. Dr. E. O. Swartz, in this same laboratory, is concerned with the manufacture and investigation of a series of penetrating organic dyes for the treatment of chancroids. The treatment of chancroids depends largely upon an attack against the infection in its localised area in the tissues, in which the specific bacilli of Ducrey are deeply buried. The drugs used at present are ineffective because of their lack of penetrability. By the use of organic dyes, to which antiseptic groups have been chemically bound, Dr. Young and Dr. Swartz are securing non-irritating and non-toxic drugs of deeper penetration and of much greater sterilising value than others now in use, thus effecting much more rapid cures. Finally, in this same laboratory, working with Dr. Young, Dr. William Jack is developing simpler technique and more effective and less expensive drugs for the treatment of venereal diseases. The venereal prophylaxis in present use depends upon drugs and apparatus available only in especially equipped stations and tedious in administration. The purpose of this investigation is to procure a preventive more easily applicable and less expensive. The relatively little progress in the perfection of venereal prophylaxis made since the discoveries of Metchnikoff and Roux, 1905, especially justifies an investigation concerned with the production of simpler and more effective methods.

Massachusetts.—An appropriation has been made to the Massachusetts State Psychiatric Institute for two investigations that are being carried out under the direction of Dr. E. B. Southard. The first of these researches is concerned with the changes effected in the central nervous system by the treatment of cases of neuro-syphilis. This investigation involves an elaborate and final study, by present methods, of the tissues, especially the nervous system, of subjects who have been treated for neuro-syphilis systematically and intensively. The Massachusetts State Psychiatric Institute possesses in its own laboratory about a hundred brains and spinal cords of subjects of neuro-syphilis who have been intensively treated by various methods, intravenously by salvarsan, arsphenamine, mercury, and iodides, by spinal injections of various drugs, by intracranial and intraventricular injections, and by combination of these methods. This clinic is, perhaps, the most elaborate of the neuro-syphilitic clinics to be found anywhere in the world at the present time; the amount of autopsy material therein is unique and its quality very special on account of uniform methods of observation of material, and especially on account of the availability of all the spinal cords as well as the brains and other tissues of the cases. This material is supported by elaborate clinical histories and records which have been collected in a readily available way. The cases have been systematically and intensively treated. In addition to the hundred nervous systems of these systematically treated cases, there are several hundred other nervous systems, equally well preserved and associated with clinical records, in untreated and partially treated cases, both of the asylum group and of the psychopathic hospital group. In addition to this autopsy material, there is a large amount of cerebro-spinal fluid material derived from the systematic neuro-syphilis treatment investigation carried on under the Commission on Mental Diseases since 1914. The second investigation under Dr. Southard's direction is a research on the family of the syphilitic (Social and Economic Effects of Syphilis in Special Relation to the Family). The clinical material available in the Massachusetts State Psychiatric Institute is unique and permits the establishment of a model plan for reaching "syphilis of the innocent" from a hitherto socially concealed source. The established ward and out-patient services available to the Psychiatric Institute yield a large number of neuro-syphilitics (paretics, tabetics, and atypical forms) yearly. In this research Dr. Southard is dealing mainly with the handling of the syphilitic family for the prevention of further infection, and for the treatment of those already infected to prevent further syphilis. The social service problems involved are of extreme difficulty, and the technique is somewhat intricate, requiring rather expert scientific social workers. The information, resulting from this investigation will indicate the size of the problem, its cost to the community, and the best methods of handling the situation. The information so secured could be put into a form available to all social agencies, and particularly to those working in child-welfare agencies and hospitals. In the John McCormick Institute for Infectious Diseases Dr. R. D. Herrold, under the direction of Prof. L. Hektoen, is making an investigation for the establishment of a better and more definite standard of cure in the gonorrhœal infection of the male. These investigators are attempting to improve the so-called provocative test, as well as the methods now in use for the cultivation of the gonococcus, and to correlate the results of fixation and other serologic tests.

Michigan.—At the University of Michigan, Dr. A. S. Warthin is engaged in a three-year programme to perfect the method and shorten the time required for the staining of spirochætes in tissues. The success of Dr. Warthin's research will provide an accurate diagnosis of latent syphilis now seldom recognised. These researches are being carried out in the Pathological Laboratory of the University of Michigan. With Dr. Warthin is associated a staff of nine investigators and assistants engaged in this research.

Minnesota.—Three researches are being carried out in the University of Minnesota. One of these investigations, under Dr. W. P. Larson and Dr. J. F. McClendon, is being undertaken in the Laboratory of Bacteriology and Immunology and is concerned with a study of the permeability of bacterial membranes, particularly of the organisms of venereal diseases. The second investigation in the Laboratory of Experimental Medicine under Dr. L. G. Roundtree and Dr. Charles E. Nixon, is concerned with the chemical and physical properties of the cerebro-spinal fluid in the luetic and non-luetic. The third research, under Dr. A. D. Hirschfelder and Dr. H. G. Irvine in the Laboratory of Pharmacology, and in the Clinics of Dermatology and Syphilis, is concerned with an investigation of phenol-alcohol derivatives in relation to their antisepsis and the chemotherapy of the gonococcus and spirochæte. There is a reason to believe that the phenol group may combine a definite antiseptic power with low toxicity, and that higher derivatives may be synthesised in which these characteristics will be greatly enhanced.

Nebraska.—At the University of Nebraska College of Medicine, Dr. Edwin G. Davis and his associates are attempting to develop a new internal urinary antiseptic, and are investigating the value of certain aniline dyes in the treatment of gonorrhœa. These researches at Nebraska are very like those that are being carried out in the Brady Urological Laboratory at the Johns Hopkins Medical School. In the previous studies carried out by Dr. Davis it has been possible to establish a definite relationship between the chemical structure and renal excretion, and to predict with reasonable accuracy which drugs would be likely to be excreted. It has further been possible so to modify these compounds chemically as to produce an antiseptic compound excreted by the kidney—an internal and urinary antiseptic which was experimentally successful. Dr. Davis is investigating these compounds with a view to determining their power of penetration through the urethral mucosa while determining other antiseptic properties both in vitro and in the urinary tract.

Stanford.—Dr. R. L. Rigdon and Dr. A. S. Spalding, in the Gynæcological and Genito-urinary Laboratory of Leland Stanford University Medical School, are searching for a more effective treatment in acute and chronic gonorrhœa. They are devising ways of supervising their patients, investigating systematically new methods of treatment and checking efficiency by bacteriological examinations. In the neurological laboratory Dr. H. G. Hehrtens and Dr. Thomas Addis are conducting a research on the permeability of the meninges to antisyphilitic drugs and are attempting to find methods of treatment that will increase this permeability. Their plans contemplate an induced permeability through the intraspinous injection of autoserum. In the Dermatological Laboratory of the Stanford University Medical School, Dr. H. Alderson is searching for more effective methods of treating syphilis. He is checking up his methods with frequent repetitions of the Wassermann test and is investigating the "provocative Wassermann." Dr. R. A. Kensella is directing an investigation covering the bacteriology of the gonococcus—its growth peculiarities, its classification, its immunising properties, and its mode of infecting experimental animals. The programme of this research includes a study of the agents, biological or chemical, which neutralise the activities of the gonococcus or relieve its established effects. It is proposed to devote two or three years to the whole programme as outlined. This research under Dr. Kensella is being carried out in the Laboratory of Experimental Medicine at the St. Louis University School of Medicine.

Albany.—Two researches are being carried on in the Albany Medical College of Union University. One, under Dr. T. Ordway in the Departments of Physiology and Chemistry and the Laboratory of Physiological Chemistry, is concerned with the nature of the Wassermann reaction. Dr. Ordway writes that from the scientific standpoint there has been a marked change in our opinions concerning the Wassermann reaction. It was at first supposed that anti-bodies were present in the blood which united with the specific antigen. It was later found that organs from non-syphilitic persons and certain lipoid substances possessed antigenic properties; indeed, that such substances were more certain in their action than antigens made from pure cultures of the specific infectious agent, the *Treponema pallidum*, when obtained in vitro. It is not clear whether the Wassermann reaction is a specific, so-called immunity reaction, or whether it is a delicate biological indication which represents measurable chemical changes in the body fluids as a result of syphilitic infection. The second of the researches at the Albany Medical College is under the direction of Dr. George S. Graham, who, with his associates in the Department of Pathology and Anatomical Laboratory and the X-ray Research Laboratory of the General Electric Company of Schenectady, is attempting to produce generalised infection in lower animals with the *Treponema pallidum* or the gonococcus. If the attempt is successful, these investigators propose to take up a pathological study of the lesions produced.

Washington.—Two researches are being carried out at the Washington University School of Medicine—one under Dr. M. F. Engman, Department of Medicine, Division of Dermatology and Biological Laboratories; the other under Dr. J. C. Jeans, Department of Pædiatrics. Dr. Engman, with his associates, is working to determine the status, if possible, of the latent syphilitic as a means of conjugal infection. He is attempting to obtain the exact clinical status of each individual patient with latent syphilis and to make a biological investigation of each of those patients to determine if the live *Spirochæta pallida* exist in the blood stream in the lymphatic glands of women with latent syphilis and in the semen of men with latent syphilis. Dr. James and his associates are making histologic examinations of a large number of placentæ for evidence of syphilitic involvement, comparing these findings, wherever possible, with the Wassermann reaction of the mother's serum and with a later clinical and serological examination of the infant. They hope to establish on a more accurate basis the value of placental examination in determining the presence of syphilis in the infant. They are collecting also tests from necropsy material of all married males 50 years of age or less. This material will be examined for spirochætes in those instances in which family studies are more or less complete.

Pennsylvania.—Dr. Bertha M. Maine and Dr. Rose Hirshler, of the Woman's Medical College of Pennsylvania, are making a serological study of syphilis in pregnant women and new-born children, with especial reference to the efficacy of the accepted methods of syphilitic treatment. They are studying the prevalence of syphilis among mothers and the new-born; investigating the subject of non-specific complement fixation during pregnancy; making a comparative study of serological and histological examinations of the placenta for syphilis, stating the comparative value of the accepted methods of specific treatment before and after delivery; searching for additional data on the time of the first appearance of the syphilitic reagin in the blood of the new-born; and seeking to determine if therapeutic benefit can be derived for the infant from the mother's milk.

Wisconsin.—An appropriation has been made to the University of Wisconsin enabling Dr. A. S. Loevenhart, Director of the Department of Pharmacology and Toxicology, to search for various compounds of arsenic and mercury which might be synthesised and be soluble in lipoids, and therefore show a predilection for the central nervous system. The object is to discover more efficacious drugs in syphilis of the central nervous system. Dr. Loevenhart and his collaborators at the University of Wisconsin are working in coöperation with Dr. W. Lee Lewis, professor of chemistry, Northwestern University, and to Dr. Roger Adams, professor of organic chemistry, University of Illinois. Dr. Lewis and Dr. Adams are engaged in research for new synthetic compounds carrying arsenic, the therapeutic values of which will be tested by Dr. Loevenhart.

Yale.—In the Brady Laboratory of Pathology and Bacteriology of the Yale School of Medicine in affiliation with the New Haven Hospital, Dr. M. C. Winternitz and Dr. G. H. Smith, with a group of assistants, are carrying out two researches. The first of their investigations is an intensive study of methods for the isolation and identification of the gonococcus with a view to the determination of the homogeneity and heterogeneity of strains and their ætiological relationships. This investigation will involve (1) the development of a more readily applicable and certain method of cultivation and identification of the gonococcus; (2) a study of cultural characteristics of the strains; (3) a study of serological reactions of the strains, with (4) particular reference to the serological properties of strains present in cases where vaccine therapy is inefficient. The second research being carried out by Dr. Winternitz and Dr. Smith is concerned with the demonstration of the syphilitic nature of unusual lesions encountered at the post-mortem table. With the elaboration of methods for the demonstration of the *Treponema pallidum* in tissues it will be possible to investigate (1) presumptive lesions of syphilis more thoroughly, and (2) the occurrence of *Treponema pallidum* without manifest anatomical changes in tissues, and an attempt to explain according to the morphology of the ætiological agent the foreign body type of reaction encountered in tertiary syphilis.

Concluding Summary.

In presenting this series of references to investigations which are being encouraged through grants of Federal funds, Dr. Snow and Dr. Storey state that it has been their purpose to illustrate lines of research which give promise of yielding new knowledge of very great value to the economic and social welfare of mankind, and particularly to the succeeding generations. The members of the Association for the Advancement of Science have it in their power to accelerate the campaign for the conquering of the venereal diseases, first by studies of the life-history of the infecting agents of these diseases and of their epidemiology; second by more actively participating in the development of a sound public opinion in support of a broad practical programme for combating them.

MEDICINE AND THE LAW.

The "Neglect" of Feeble-minded Children.

REFERENCE was made in THE LANCET of Feb. 21st (p. 468) to a case in which Mr. Justice Greer, sitting as vacation judge, made orders which had as their effect the handing back to the custody of his parents a youth, 20 years of age but mentally defective, who was being treated in an institution through the action of the Sheffield Corporation. The question raised by that body as the local statutory authority under the Mental Deficiency Act, 1913, is one of considerable importance to similar authorities desirous of making the Act effective within their jurisdiction. The lad concerned was admittedly a fit subject for institutional treatment on account of his mental condition, and his care had been undertaken by the local statutory authority without opposition from the parents, who, however, had apparently changed their minds and desired to have their son back in his home. The short question for decision was whether the corporation could resist that application on the ground that he was "found neglected" within the meaning of Section 2 of the Act when they took him over. It was not alleged that he was being "neglected" in the sense of being left by his parents without proper lodging, or food, or clothing. It was not, in short, a case of "neglect" such as is to be found in the cases of cruelty to normal children with which we are familiar. He was, however, receiving no special treatment or training, and the case for the local statutory authority was rather that, as applied to a mentally defective person under 21, the word "neglect" would be satisfied if there were a lack of such care, attention, and education as the institution offered would supply.

The importance of the case, of course, lies in the fact that there are many mentally defective children in working-class homes who are either becoming worse or, at any rate, are losing all chance of improvement such as an institution would afford. Their parents are quite kind to them and do their best for them, but are unable to improve their condition. They are perhaps fond of them, and in any event are unwilling to part with them. The second section referred to, where it is applicable, gives power to deal with a defective "who is found neglected, abandoned, or without visible means of support, or cruelly treated." The same words are used in a later section of the Act (Section 15), which enables a constable to take to a place of safety a person whom he believes to be a defective and whom he finds "neglected, abandoned, or without visible means of support, or cruelly treated." Read together these expressions certainly leave doubtful the meaning which the Sheffield authority, actuated by a perfectly right and praiseworthy public spirit, sought to apply to the word "neglected."

In the present case there has been no further resistance. The orders nisi made upon writs of certiorari and habeas corpus by Mr. Justice Greer have been made absolute without opposition. This leaves the matter as a decision of a particular judge upon particular facts before him. If at any future time a local statutory authority under the Mental Deficiency Act gets a similar order made against it, or one in its favour, and the making absolute of the rule is opposed, the court will, no doubt, decide whether "neglect" in the case of a "mentally defective" differs from "neglect" as applied to the case of a normal child. The public and the legislature will then agree whether it is desirable that the law should be amended in the direction of increased efficiency or whether the prejudices of parents should prevail. They are natural and excusable prejudices, but they are certainly undesirable in the interest of the defective person.

Drunkenness as a Defence in Trials for Murder.

The House of Lords allowed recently an appeal from the Court of Criminal Appeal which had quashed a conviction for murder and had substituted a verdict of manslaughter in the case of R. V. Beard. Beard, being drunk, killed a child of 13 when committing rape upon her through suffocating her in the attempt to prevent her from screaming. The question for determination by the House of Lords was in what circumstances drunkenness can be taken into consideration for the purpose of reducing the crime of murder to manslaughter. The judgment delivered by the Lord Chancellor will be found reported at length in the *Times* of March 6th by those interested in a question which must always be closely associated with, and determined by, medical evidence. Without following the Lord Chancellor in recapitulating the history of the law regarding insanity and drunkenness as defences, and in the consideration of the precise extent to which the summing up in this particular case was defective, we may state briefly that the judgment in Beard's case may be taken to decide authoritatively that: 1. Insanity produced by alcoholism, such as an attack of delirium tremens, is to be distinguished from drunkenness, and that the tests laid down in 1843 in McNaughton's case are to be applied only when the former has been proved, and not in cases of drunkenness. 2. Evidence of drunkenness rendering the accused incapable of the intent essential to constitute the crime should be taken into account with other facts proved in order to determine whether or not he had that intent. 3. Evidence of drunkenness falling short of that indicated in (2) and establishing merely that his mind was affected by drink so that he more readily gave way to some violent passion does not rebut the presumption that a man intended the natural consequences of his acts.

In applying these principles to the case of Beard the Lord Chancellor pointed out that drunkenness could be no defence unless it could be established that Beard at the time of committing rape was so drunk that he was incapable of forming the intent to commit it, which was not the fact, and having regard to the evidence could not be contended. It was doubtful, in his lordship's opinion, whether there was any sufficient evidence to go to the jury that the prisoner was in any relevant sense drunk at all. There was certainly no evidence that he was too drunk to form the intent of rape, and an act of violence in furtherance of that felony was the cause of death. Such a killing was by the law of England murder. The appeal consequently was allowed and the conviction of murder restored, but it is understood that the capital sentence originally passed will not now be carried out.

The Contract in Panel Practice.

In a series of letters to the *Medical World* Mr. Adam Fox has criticised the position with regard to panel practice. He comments adversely upon the views of the authorities with regard to the disposal of goodwill in relation to panel practice and the attendance upon panel patients in emergency by other doctors at the cost of a medical man absent when summoned by a patient. He will have found many sympathisers in the views he expresses on these and other points. The lowering of the maximum number of patients to be on the list of any one practitioner, for example, is not likely to be welcomed by those whose lists exceed or are beginning to approach the maximum recommended. There is, however, one point where it is not at all clear that Mr. Fox is right, not merely in his opinion but in the reason which he gives for it. He is insistent in urging that the law courts should be open to practitioners signing contracts with Insurance Committees in disputes arising out of their fulfilment, and complains that "the right of appeal to the courts on the merits of a case is still refused. (It exists on a question of procedure mainly.)" We feel doubtful as to this grievance, and are not convinced of the wisdom of submitting to judges, or judges and juries, questions which are now sifted thoroughly by persons who, whatever their shortcomings, are familiar with their subject. We doubt if medical practitioners would find the change satisfactory. If, however, Mr. Fox is entitled to put forward a contrary opinion we venture to question the reasoning by which he supports it, and emphasises his advice to practitioners to refuse to sign the agreement, or contract, with an Insurance Committee. This we find dwelt upon in a letter published by our contemporary on Oct. 5th, 1917, and now reprinted in the form of a circular. "A contract," Mr. Fox writes, "is an agreement upon fixed terms, involving consideration and compensation made between responsible parties, and is therefore enforceable by law." "The document signed is not a contract." "The British Constitution gives every British subject the inherent right of having the law courts thrown open to him, and which even an Act of Parliament cannot take from him." This may be arguable within limits, but though the great majority of contracts are enforceable at law, we are all of us familiar with others which are not, and the right to enforce which has been expressly taken away by Acts of Parliament. It is a different matter to advise that "the only safe course for panel practitioners is to refuse to sign any document which is not a contract enforceable at law." Once signed, as matters stand, the contract precludes recourse to the law courts. If, however, a combined refusal to accept such contracts is urged, it must, on the other hand, be remembered that tribunals are provided to take the place of the law courts, which some may regard as better equipped for the purpose, and that, secondly, this has been done to enable the patients of panel practitioners to secure a hearing of their grievances without the expense and formalities attendant upon legal proceedings. In estimating the probability of success following upon such combined resistance as Mr. Fox urges, this latter point should be carefully considered.

FATAL ACCIDENT TO A RAND DOCTOR.—Dr. Donald Macaulay, a well-known medical man on the Rand, was killed by his own motor-car in Johannesburg on Jan. 27th. It is presumed that he must have cranked up the car in gear, with the result that it knocked him down and pinned him underneath, where he was found next morning. Dr. Macaulay was a graduate of Edinburgh University, for which he retained a great affection, and one of his sons is at present a medical student there. He had for many years been in charge of the health of the natives employed at the Geldenhuis Deep and other mines, and of a large native hospital. When a member of the House of Assembly for Denver his constituents were mainly miners, with whom he was very popular, and he lost no opportunity of furthering their interests in the House. He also instituted a campaign in favour of the compulsory medical inspection of children in the schools. During the war Dr. Macaulay served on a hospital ship in the German South-West Africa campaign, and afterwards in the Mediterranean. During the operations in German East Africa he was in charge of the hospital ship *Ebani*, which was fitted out under his supervision. Dr. Macaulay was one of the best known and most popular figures on the Rand, and will be greatly missed.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

METEOROLOGICAL OFFICE: ADVISORY COMMITTEE ON ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING

Oct. 31st, 1919.

Place.	Rainfall in millimetres.	Metric tons of deposit per square kilometre.

There were no returns during the month of October from the following stations: London (Ravenscourt Park), the results bei omitted as doubtful, and the two stations at Manchester. In November, again, there were no returns from the Manchester stations, an also Newcastle-on-Tyne and Rochdale, while at three Glasgow stations (Alexandra Park, Blythswood-square, and Victoria Park) th bottles containing the rainfall were broken by frost. Lead was reported present in the insoluble matter of the Glasgow specime examined.

"Tar" includes all matter insoluble in water but soluble in CS$_2$. "Carbonaceous" includes all combustible matter insoluble in wat and in CS$_2$. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Appro 9 lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) 1 g. per sq. metre; (*d*) 1/1000 mm. of rainfall. Tr. = Trace.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involv remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Offi are made in THE LANCET Laboratory.

URBAN VITAL STATISTICS.

(Week ended March 6th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons for the middle of last year, the annual rate of mortality, which had been 16·2, 15·6, and 16·4 in the three preceding weeks, rose to 16·9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 17·4, or 0·4 per 1000 above the revised rate recorded in the previous week, while among the remaining towns the rates ranged from 5·7 in Carlisle, 8·6 in Eastbourne, and 9·0 in Cambridge, to 25·7 in Leeds, 26·4 in Aberdare, and 27·1 in Liverpool. The principal epidemic diseases caused 486 deaths, which corresponded to an annual rate of 1·4 per 1000, and comprised 210 from measles, 109 from whooping-cough, 87 from diphtheria, 53 from infantile diarrhœa, 23 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 2·6 in Grimsby and in St. Helens, 3·1 in Gloucester, and 5·0 in Barnsley; whooping-cough of 1·2 in Stockport, 1·4 in Birkenhead, 1·6 in West Hartlepool, and 1·7 in Lincoln; and diphtheria of 1·7 in Leyton and 1·8 in Hastings. The deaths from influenza, which had increased from 66 to 178 in the five preceding weeks, rose to 196, and included 54 in London, 27 in Birmingham, 14 in Leeds, 10 in Liverpool, and 7 in Manchester. There were 2255 cases of scarlet fever, 2006 of diphtheria, and 7 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2316, 2026, and 4 respectively at the end of the previous week. The causes of 43 deaths in the 96 towns were uncertified, of which 9 were registered in Birmingham and 3 each in London, Liverpool, South Shields, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with a aggregate population estimated at 2,400,000 persons, th annual rate of mortality, which had been 14·7, 14·2, and 15 in the three preceding weeks, was again 15·7 per 1000. Th 337 deaths in Glasgow corresponded to an annual ra of 15·8 per 1000, and included 5 each from measles, whoopin cough, diphtheria, infantile diarrhœa, and influenza, and from scarlet fever. The 79 deaths in Edinburgh were equ to a rate of 12·1 per 1000, and included 2 each from measl and infantile diarrhœa and 1 from diphtheria.

Irish Towns.—The 165 deaths in Dublin corresponded to a annual rate of 20·7, or 1·2 per 1000 below that recorded the previous week, and included 7 from whooping-coug 4 from influenza, 3 from diphtheria, and 1 from infanti diarrhœa. The 214 deaths in Belfast were equal to a rate 27·0 per 1000, and included 12 from influenza, 4 each fro measles, scarlet fever, and whooping-cough, 2 each fro enteric fever and infantile diarrhœa, and 1 from diphtheria

---

BIRMINGHAM DENTAL HOSPITAL.—The annu report of this hospital, of which Sir William Bowat is the President, shows an adverse balance on the yea working of £248. In the forthcoming year at least 12 ne dental operating chairs, at a cost of about £450, will required, and the increase in the number of students w have to be provided for. The report of the surgical committ states that conservative operations for the preservation the natural teeth and combating disease have greatly i creased in number. There are signs of a large influx students to the institution, the centre of dental treatme in the Midlands, and it is hoped that the Government a subscribers of the hospital will spare no effort to ass them in the provision of facilities for the training of the men.

THE DIAGNOSIS OF MALARIA.

To the Editor of THE LANCET.

SIR,—The publication of a letter from Colonel Mathew O'Connell in your issue of Feb. 28th and your annotation upon the probability-diagnosis of malaria calls for some reply from myself, as it was my article upon the necessity for early diagnosis and early treatment of malaria in armies in the field which prompted this correspondence. In the first place, I think it is a pity that anyone should throw cold water at the present moment upon microscopic diagnosis, which has been proved to be the most important and necessary and reliable means of diagnosis in malaria with a view to treatment; for if this is not the object of Colonel O'Connell's letter I fail to understand the issue that is at stake, nor can I see how the classical experiments of Sir Patrick Manson have any bearing upon microscopic diagnosis as applied to military medicine during the war in Palestine. I am sure Colonel O'Connell will admit that, by instituting a system of microscopic diagnosis in the field, many valuable lives were saved which would otherwise have been lost through non-administration of quinine, nor can I estimate how much military disability was thereby avoided. There can be no question, I submit, that everyone who served with the armies in the East during the war fully appreciated that a microscope and an expert pathologist—for a microscope without a trained eye behind it is of little use—are as essential a part of the field ambulance equipment as are surgical instruments, stethoscopes, or the nevitable cholera outfit which is so carefully treasured, but seldom used. How many hundred diagnoses of malaria, which would otherwise have been missed on clinical grounds, were made during these epidemics of subtertian malaria I would not like to guess, but whenever the clinical diagnosis became unsatisfactory in the midst of phlebotomus fever, influenza, relapsing fever, and enteric, the man with a microscope scored every time.

I remember standing in a casualty clearing station one morning in December, 1917, when a large number of sick filed past bearing upon their field cards such varied diagnoses as debility, bronchitis, influenza, pleurisy, disordered action of the heart, and what not, and how I found on microscopical examination no less han 22 were virulent infections with the subtertian parasite. This rapid examination occupied less than half an hour, but it is more than possible, since malaria had not been suspected at that season of the year, that ll these men would have been evacuated down the ine and would not have received specific quinine treatment till some two or three days later, and possibly one r more would have succumbed.

One has only to glance at the official report upon malaria in Palestine during 1918 in order to convince neself that the early microscopic diagnosis of malaria helped to conserve the man-power of Allenby's force uring that fateful summer, and I do not think it is an xaggeration to claim that nearly a division of European roops was spared by these means for the great advance n September of that year. From official sources it is nown that no less than 35,439 cases, or one-tenth of the otal force, were microscopically diagnosed as malaria uring 1918, and of these no less than 24,748 were erified by eight laboratories and diagnosis stations rimarily near the front line, 14,842 being benign and 906 subtertian infections. The total number of blood xaminations undertaken by these field laboratories and iagnosis stations was 111,261, a third of the total ghting force, in a period of less than six months.

During the advance into Syria the number of cases of evere or malignant malaria reached the colossal figure f 1800 fresh infections a week. Even this figure annot be taken as comprising the total number, as wing to the rapidity of the advance complete microscopic diagnosis became impossible. Even the differentiation of the two main forms of malaria—for instance, the benign, which seldom, if ever, kills—from the subtertian, which proved to be responsible for nearly 800 deaths in 1918, should alone justify the adoption of a microscopic diagnosis in every case of pyrexia. I am willing to grant that a very small proportion of cases may not be diagnosed on one microscopic examination alone owing to scantiness of the parasites in the peripheral blood or the early stage of the disease; but one's chances are greatly increased if a three-slide rule on three separate occasions, or even the thick film method, is adopted. It was by the institution of a routine of this kind that many benign cases (some 3000 in all) were retained for further service near the front line instead of being sent to hospital at the base, as would otherwise have been the case.

Colonel O'Connell quotes me as saying that three cases originally diagnosed as sunstroke, five as dysentery, &c., were afterwards found to be suffering from subtertian malaria—a very small number in so large a force. This is hardly correct. I quoted no numbers of the total misdiagnoses, but only gave instances where the discovery was made too late—on the post-mortem table! I would like to cite one instance in this connexion. After the occupation of Damascus one pathologist reported 11 out of 15 patients isolated as dysentery, and 30 out of 45 diagnosed as influenza were in reality subtertian malaria, in one field ambulance alone. This by no means exhausts an extensive list of critical medical and even surgical cases in which the diagnosis and treatment were made clear by simple microscopic examination. I have seen three cases sent down as lunatics, two of which were fatal subtertian infections, and one man under arrest for suspected drunkenness for the same reason.

After the adoption of the diagnosis station scheme in the E.E.F. I find from my records of over 100 autopsies on malarial cases that in no single instance had the existence of the infection been missed during the victim's lifetime. This certainly was not the case before the adoption of the scheme.

I do not think it is claiming too much to say that field laboratories more than justified their existence in the E.E.F.; at any rate, they assisted in making a diagnosis in at least 80 per cent. of medical cases. The amount of work they got through was phenomenal. In the last laboratory to which I was attached two officers and three men were responsible for over 62,000 reports on blood and fæces, including over 500 blood examinations for malaria in one day, during the year 1918. One of the great advances in clinical medicine has undoubtedly been our ability to diagnose malaria infections with precision, and, again, I hope that Colonel O'Connell's letter will not lead to the diminished use of the microscope in malaria diagnosis; even in the case of patients in this country I know of cases in which, for want of a microscopic examination, the real cause of death or illness—malaria—has been overlooked.

I am, Sir, yours faithfully,

PHILIP MANSON-BAHR.

Weymouth-street, W., March 1st, 1920.

THE SITE OF INOCULATION IN SYPHILIS.

To the Editor of THE LANCET.

SIR,—Having read the investigations on syphilis which have been conducted by Dr. P. Fildes and Surgeon-Lieutenant Commander R. J. G. Parnell at Haslar Hospital (Medical Research Committee, Special Report Series, No. 41 and 45 [see p. 614]), I asked the writers if they could supply me with data regarding the sites of inoculation of their patients. In response Dr. Parnell has most kindly supplied me with the data of 2743 consecutive cases of the Haslar series. It will be seen that 68·7 per cent. of patients are infected on the prepuce, glans, or meatus (4·4 per cent. under a phimosed prepuce), 10·6 per cent. on the body or root of penis or on the scrotum, 19 per cent. unstated or combined lesions, and 1·7 per cent. extragenital lesions.

These facts were supplied with the permission of the Medical Director-General of the Navy; and, as I think they are of general interest to the medical profession at the present time, I have asked and obtained leave to publish the table which is herewith appended.

I am, Sir, yours faithfully,
DOUGLAS WHITE,
Honorary Secretary, National Council for Combating Venereal Diseases.
Avenue Chambers, Southampton-row, London, W.C.,
March 2nd, 1920.

ENCLOSURE.

Sites of Inoculation Lesions in 2743 Cases of Syphilis.

From the Indexed Records at R.N. Hospital, Haslar, by Surgeon-Lieut. Commander R. J. G. PARNELL, R.N., Specialist in Venereal Diseases, Haslar.

Genital Inoculation Lesions.

In urethra (concealed)	2	In sulcus	420
Within meatus (concealed)	25	On prepuce (skin 328, mucous membrane 346)	674
At meatus (visible)	94	On frænum preputii	192
On glans penis	270	Phimosed prepuce (concealed)	121
On corona glandis	86		

Total, 1884 = 68·7 per cent.

Body of penis	209	Scrotum	20
Root of penis	50	Peni-scrotal angle	13

Total, 292 = 10·6 per cent.

Site on penis not stated	238	Combinations of above	283

Total, 521 = 19 per cent.

Extragenital Inoculation Lesions.

Lip	20	Finger	2
Eye (palpebral conjunctiva)	3	Umbilicus	1
Anus (at or near)	7	Nose	1
Thigh	2	Neck	1
Pubes	6	Abdomen	1
Chin	1	Buttock	1

Total, 46 = 1·7 per cent.

Remarks.

1. In addition, 101 cases had manifest signs of syphilis or had cerebro-spinal syphilis, yet no site of the inoculation lesion was found; all the men denied a sore on the penis. A few of these men gave a history of "gonorrhœas." The majority denied having had V.D. in any form, *but admitted risks of infection.* A very small number denied V.D. and stated that they had never exposed themselves to infection. Three of these had definite signs of congenital syphilis.
2. One case of genital and extragenital inoculation lesions occurred (lip and penis).
3. Of the 238 cases in which the site (on penis) was not stated, the vast majority of these were old infections giving a definite history of a sore on the penis, but no scar was found. In a few cases there was an indefinite amount of scarring at a site other than that at which the sore apparently had been.
4. 46 cases were extragenital—1·7 per cent.

MYALGIC PAINS AND MANIPULATION.

To the Editor of THE LANCET.

SIR,—At the risk of appearing tedious I would like to add a few words to Mr. Haldin Davies's letter which appeared under the above title in your issue of Jan. 10th. Mr. Davies says that there is "something in manipulative surgery"; with that conclusion I cordially agree. No one was more opposed than myself to any recognition of or concession to unqualified practitioners, but when case after case drifted off to the manipulative surgeon only to return cured it gave me furiously to think. Much against my inclination I am compelled to admit that the manipulative surgeon possesses some skill which I and possibly some of my professional colleagues lack.

So many cases of displaced cartilage and deranged joints have been put right by simple manipulation when I and others had failed that I am bound to confess that such patients were well spared the operation that had been suggested. It seems a pity that the profession declines to investigate these problems. The proposition is a simple one: either the manipulative surgeon possesses some special skill of which the public and the profession should have the benefit, or a large number of medical men and a larger number of the public have been hopelessly misled. It is difficult, if not impossible, to accept this latter alternative.

The whole matter could easily be cleared up by an investigating committee, and I am not by any means alone in wishing to have this done. Believing, as I do, that many cases of deranged joints can be submitted successfully to manipulation, which I myself cannot practise, am I justified in advising an operation of definite risk and of somewhat uncertain result until these milder manipulative measures have been tried?

I am, Sir, yours faithfully,
March 6th, 1920. W. H. CLAYTON-GREENE.

BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—Had I known that my letter would be published I should have asked you to spare me space to go into details, for which a mere acknowledgement did not seem to call. I entirely endorse the admirable letter of Major W. H. Broad, who, I may say, has had an exceptionally wide experience of the work of the blind masseur, and whose admirable orthopædic work is known to most members of the medical profession.

For reasons which I am free to confess do not seem entirely convincing to myself, or to many eminent medical men, it has been thought fit to impose limitations upon the examinations in remedial exercises which are set to blind students, and this in spite of the fact that a totally blind man passed the full examinations set to sighted folk, and not only passed them, but was first in the list. This blind man has exceptional ability, and perhaps the full examination might be rather beyond the scope of some blind masseurs. At the same time, the examination which is set them renders a man who passes it quite proficient, for all ordinary requirements, and would prove amply sufficient for any but very special cases.

I very much fear that the publication of my letter in your last issue may lead your readers to suppose that I do not possess full faith in the qualifications of the blind masseur. This is very far from being the case. The blinded soldiers who have been trained in this most useful profession are giving complete satisfaction in al parts of the British Empire; indeed, I go so far as to say that wonderful as the successes of St. Dunstan's have been, the success of those of its inmates who have been trained in massage is the most wonderful of all.

I am, Sir, yours faithfully,
ARTHUR PEARSON,
Chairman, Blinded Soldiers' and Sailors' Care Committee
President, National Institute for the Blind,
224, Great Portland-street, London, W.
St. Dunstan's, Hanover Gate, Regent's Park, N.W.1,
March 6th, 1920.

*** We could have no idea that Sir Arthur Pearson did not intend his letter for publication. Like him we have every sympathy with the blind students, and are aware of their exceptional qualities in many directions. The annotation indicated a place in the masseur' work where the blind must, in our opinion, be handicapped, and that view is unaltered.—ED. L.

TREATMENT OF CARBUNCLES, BOILS, ETC
BY LARGE DOSES OF DILUTE SULPHURIC ACID.

To the Editor of THE LANCET.

SIR,—On March 15th, 1913, I called attention in TH LANCET to the great success of the dilute sulphuric aci treatment in the above-mentioned conditions an staphylococcic infection generally. Since the dat mentioned I have had some very severe cases to dea with, which have resisted all ordinary remedies, including injections with serum, but have yielded completely to the sulphuric acid treatment.

Only three weeks ago I had a most inveterate cas of acne sent to me of 20 years' standing, which ha been treated by all the ordinary means and for the las few years by repeated injections of serum without an benefit. I put this patient at once on 30-minim doses dilute sulphuric acid (made by adding 3 fluid ounces of th strong acid to 29 fluid ounces of water) and the resu has been a complete cure in three weeks. Th particular patient was covered over the whole bod from head to foot with pustules and was a splendi example of the power of this simple remedy whe given internally and in sufficient doses (i.e., ♏ xx. ♏ xxx.) also of the right strength.

As I said in my former communication to you journal, smaller doses of a weaker strength of the aci are of no use whatever. The 30-minim dose, dilut with a wineglassful of water is, in my experience over 40 years, always well tolerated, and has, witho exception, always proved successful. My son, D

Russell J. Reynolds, who has returned from active service in India, tells me it is being used by some of the medical officers there with the best results. I feel that in all cases of suppuration it should at least be tried. My reason for writing again on this subject is that this mode of treatment does not seem even now to be sufficiently well known.

I am, Sir, yours faithfully,
J. REYNOLDS, M.D. Brux., M.R.C.S.

Brixton-hill, S.W., March 6th, 1920.

Obituary.

SAMUEL WEST, M.A., M.D. OXON., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S AND THE ROYAL FREE HOSPITALS.

THE death of Dr. Samuel West on March 2nd, at the age of 72, removes another of that band of London physicians which understood how to reconcile the claims of important teaching appointments with private consulting work, and still to find time to devote to public and benevolent purposes.

Samuel Hatch West was born at Carlisle on April 13th, 1848, the son of John West, Deputy Inspector-General of Mails to the General Post Office. He was educated at Westminster School, where he was Queen's scholar, going on to Christ Church, Oxford, where, after taking honours in Classical Moderations, he began the work of his life by studying physiology in the museum under Professor Rolleston. In this subject he took a first-class in the Final Schools. Even then his teachers recognised in him a man with a future, for, beginning as a successful pupil, he soon became a close friend of both Rolleston and Acland, and he was elected Radcliffe Travelling Fellow. Probably West's choice of St. Bartholomew's as his medical school was determined by his friendship with Rolleston. Since in those days the official course of study for the Oxford M.B. could not begin till after taking the B.A., West and his contemporaries from Oxford were what would be now called "full-time students" at St. Bartholomew's. In the preliminary subjects and in physiology he had not much to learn there, but he filled up his spare time with advanced and original work. Working under the late Dr. W. J. Russell, he designed a method of estimating the urea in urine by means of the hypobromite reaction, and later was one of the first to apply this clinically. His study of medicine proper was carried out chiefly in the wards of Dr. James Andrew. After qualification he became house physician to Andrew, and between them close bonds of intimacy developed. They were from the same university, had the same eager capacity for work and devotion to medicine, and West very early in his career became Andrew's colleague at Victoria Park Hospital. Andrew's influence upon him was seen later in his principal publications, which were on diseases of the respiratory organs and on granular kidney.

Graduating M.B. Oxf. in 1875, and obtaining the M.R.C.P. Lond. in 1877, Dr. West became assistant physician to St. Bartholomew's Hospital in 1887, and full physician 17 years later, holding, at the same time, the lectureship in the principles and practice of medicine. At the same time he was physician to the Royal Free Hospital and to the Victoria Park Chest Hospital.

One of his colleagues writes of this period of his life: "When at the Royal Free Hospital, on the illness of Dr. Buchanan Baxter, and subsequently at the Victoria Park Chest Hospital, the writer first became associated with Dr. West, he received much kindness at his hands and much help, for which the indebtedness remains. On many occasions the junior colleague was accustomed to turn to his senior for assistance in difficult clinical cases, and he never failed to be impressed by his clinical acumen, his breadth of view, and the soundness of his advice. His teaching was greatly valued by the students at the Royal Free Hospital, and in proof of this it may be stated that if they had a grievance it was that they wanted more not less of that which he had to impart. ...... As physician Dr. West was essentially the clinician, for though he came to the bedside thoroughly conversant with scientific methods, and, in particular, with an exceptional knowledge of chemistry, he avoided the shallows of the ultra-scientific application of those methods. He was a close student of pathology, and both in his outlook and in his teaching it figured prominently."

Recognised thus as teacher and clinician, Dr. West held, as was natural, at one time or another, positions as examiner at the Universities of Oxford, Cambridge, London, and Birmingham, and at the Conjoint Board. He was three times censor to the Royal College of Physicians of London. He presided over the medical and the clinical sections of the Royal Society of Medicine. He was Lettsomian lecturer and treasurer to the Medical Society of London.

And first and foremost he will be gratefully remembered for his labours to alleviate distress through the Royal Medical Benevolent Fund. Here he held office continuously from 1893, when he became honorary financial secretary. In 1899 he succeeded Sir W. Broadbent as treasurer, on the latter becoming president of the Fund. On the resignation of Sir John Tweedy in 1917, Dr. West became president until the time of his death. In this long service Dr. West became so identified with the Fund that some spoke of it as "West's Fund." As treasurer one of his first acts was to insist that all legacies should be invested to provide annuities, and he had the satisfaction of seeing the number increased from 100 to 170, while the total income of the Fund rose during his management from £3625 to over £7000. Owing principally to his exertions, consent was obtained to apply the term "Royal" to the Fund, with the name of Prince Arthur of Connaught as vice-patron. In the following year he organised the festival dinner and secured in subscriptions over £3000. Foreseeing the probable financial difficulties in which many medical men, suddenly called to join the army and leave their practices, would be placed, Dr. West initiated the special War Emergency Fund, and one of his last acts was to secure from the National Relief Fund a donation of £10,000 towards its objects. During the war he became chairman of the executive committee of the Professional Classes War Relief Council. Through this agency he was able to place valuable information regarding education at the disposal of many medical men. Only those who knew Dr. West's keen interest in these Funds can appreciate the time and care he gave to their welfare.

West was not a voluminous writer, but at each stage of his active work he contributed something to exact knowledge. His practical guide for the use of students entitled "How to Examine the Chest," appearing first in 1883, ran into three editions. His Lettsomian lectures on Granular Kidney and Physiological Albuminuria, published in 1899, were for many years a standard work of reference. A second edition of his largest work on "Diseases of the Organs of Respiration," in two volumes, was published in 1909. His smaller writings included articles, in different journals and year books, on acute and chronic nephritis, pneumothorax, sulph-hæmoglobinæmia, the amount of nitrogen excreted by man at rest, and hypertrophy and dilatation of the heart.

Of West's personal qualities it is difficult to give a comprehensive view. He was a sociable man, full of many interests. He had a great capacity for clear thinking and exposition, and also for organisation. An excellent musician and a good singer, while house physician at St. Bartholomew's Hospital he organised, along with his colleagues in office, Darbishire, Abercrombie, and Ormerod, a concert in the Great Hall which became an annual affair, and from which developed the present hospital musical society. The finer qualities of head and heart—friendliness, good fellowship, social attractiveness, wide human interests—all these West possessed in a high degree, and combined with ability, energy, and devotion to medicine, they made possible that life full of distinction and of useful work for which he will be long remembered.

Dr. West married Margaret, daughter of Sir Edward Frankland, F.R.S., by whom he had three sons and three daughters.

SIR THOMAS ANDERSON STUART, M.D., LL.D. EDIN., D.SC. DURH.,

PROFESSOR OF PHYSIOLOGY AND DEAN OF THE MEDICAL FACULTY IN THE UNIVERSITY OF SYDNEY.

THE death is announced of Professor Stuart, who was largely responsible for the existing public health legislation in New South Wales, and whose interest in his calling materially promoted the welfare and dignity of medicine in Australia.

Thomas Anderson Stuart was born at Dumfries on June 20th, 1856, the son of Alexander Stuart, Dean of Guild. He was educated at the Dumfries Academy, at the gymnasium at Wolfenbüttel, and in the Universities of Edinburgh and Strasburg, graduating M.B., M.Ch. at Edinburgh in 1880 with first-class honours and the Ettles scholarship. The following year he was appointed assistant to the Professor of Institutes of Medicine, proceeding later to the M.D. of the University, when he was gold medallist.

His name will be chiefly associated with Australia, where he spent his life from the time when he went out in 1883 to be professor of physiology in Sydney. In his new country his life was a long story of official appointments successfully discharged. He was twice president of the Royal Society of New South Wales, and among the many offices which he held were those of medical adviser to the Government and health officer for Port Jackson, president of the Board of Health, chairman of the board of directors of Royal Prince Alfred Hospital, president of the Health Society of New South Wales, president of Civil Ambulance Brigade, trustee of the Australian Museum, president of the Highland Society of New South Wales, councillor of the Women's College, president of the Zoological Society, vice-president of the Industrial Blind Institution. He took a prominent part in all public health and educational movements, and was president of the British Immigration League of Australia. He was an honorary M.D. of the Universities of Sydney and Melbourne, in 1900 was given the LL.D. by the University of Edinburgh, and later the D.Sc. by the University of Durham.

In 1914 he received the honour of knighthood in recognition of his full and valuable activities.

The Services.

ARMY MEDICAL SERVICE.

Col. N. Faichnie retires on retired pay.

Temp. Hon. Col. Sir J. Collie relinquishes his commission, and is granted the honorary rank of Lieutenant-Colonel.

ROYAL ARMY MEDICAL CORPS.

Temp. Lieut.-Col. R. P. Jack (Lieut.-Col., Sco. Rif., T.F. Res.) relinquishes his temporary commission.

Major J. H. Campbell and Temp. Capt. J. P. Davidson relinquish the acting rank of Lieutenant-Colonel.

Major H. T. Wilson relinquishes the temporary rank of Lieutenant-Colonel.

Temp. Major N. G. Cooper to be acting Lieutenant-Colonel.

Temp. Capt. F. D. Saner relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Major I. A. O. MacCarthy retires on retired pay.

Temp. Major W. C. Bosanquet (Bt. Major, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

The undermentioned relinquish the acting rank of Major: Capt. H. G. Winter; Temp. Capts. E. J. Selby, G. W. R. Rudkin, A. Scott, C. A. Brisco, L. H. C. Birkbeck, G. C. Adeney.

Temp. Capt. A. W. Wilcox to be acting Major whilst commanding troops on a hospital ship.

Capt. E. G. S. Cane to be temporary Major whilst specially employed.

G. W. Beresford, late temporary Captain, to be temporary Major.

Temp. Capt. W. J. Pearson to be acting Major.

Capt. J. W. C. Stubbs is seconded for service with the Egyptian Army.

J. G. Shaw, late Can. A.M.C., to be temporary Captain.

The undermentioned Lieutenants (temporary Captains) to be Captains: W. D. Whamond, T. L. Henderson, A. G Stevenson, R. H. C. Pryn, B. J. Daunt, A. J. Bado, H. M Alexander.

O. T. J. C. De H. Clayre to be temporary Lieutenant.

Officers relinquishing their commissions:—Temp. Majo (acting Lieut.-Col.) R. D. Hotchkiss (granted the rank of Lieu tenant-Colonel). Temporary Majors retaining the rank o Major: C. B. Dobell, J. C. Woods, C. R. Nicholson. Temporar Captains granted the rank of Major: F. D. Saner, E. S Sowerby, R. H. Strong, P. K. McCowan, J. T. Grant (actin Major), O. R. L. Wilson, W. M. Oakden, C. C. Harrison Temporary Captains retaining the rank of Captain: A. R Mitchell, W. H. Orton, A. J. R. Taylor, C. G. Lees, T Kennedy, J. Williamson, J. A. Hadfield, C. L. Herklots W. W. Halsted, G. R. Spence, P. C. H. Ryan, G. E. Kinnersly D. S. Cassidy, T. B. Marshall, A. W. Ritchie, J. T. Daly G. Cock, E. G. Y. Thom, A. Macdonald, R. S. Gibson (actin Major), M. A. Milne, W. E. Procunier, V. E. Sorapure L. Milburn, L. W. Evans, N. McA. Gregg, J. H. Jones R. J. Harley-Mason, J. R. MacNeill, R. Williams, E. C Bowden, A. J. Hawes. Temp. Lieut. D. C. Macaskill (retain the rank of Lieutenant).

SPECIAL RESERVE OF OFFICERS.

Capt. K. D. Murchison relinquishes the acting rank o Lieutenant-Colonel.

The undermentioned Captains relinquish the acting ran of Major: A. McL. Ferrie, W. J. Webster, C. E. H. Gater W. Johnson, B. Goldsmith, C. J. B. Way, R. Nixon, H. D Brown, A. Picken.

Capt. J. Berry resigns his commission.

Lieutenants to be Captains: P. S. G. Cameron, L. H Bartram.

Officers relinquishing their commissions:—Capt. E. B Jones. Captains retaining the rank of Captain: H. S. A Alexander, I. G. Innes, F. L. Heap, O. Johnston, W. Griffiths J. D. MacCormack, H. E. Rhodes, M. W. Geffen, J. A. C Guy.

TERRITORIAL FORCE.

Capt. (acting Lieut.-Col.) J. Miller relinquishes the actin rank of Lieutenant-Colonel on ceasing to be speciall employed.

Capt. (acting Major) J. B. Bate relinquishes the actin rank of Major on ceasing to be specially employed.

Capt. A. D. Kennedy is restored to the establishment.

4th London General Hospital: Capt. (Bt. Major) W. C Bosanquet is restored to the establishment on ceasing t hold a temporary commission in the R.A.M.C.

2nd Scottish General Hospital: Capt. E. Matthew i restored to the establishment.

ROYAL AIR FORCE.

Medical Branch.—Capt. O. H. Gotch and Lieut. R. H Turner are transferred to the unemployed list.

Dental Branch.—Capts. J. Jones and N. L. Smallbone ar transferred to the unemployed list.

INDIAN MEDICAL SERVICE.

Lieut. (temp. Capt.) Jagat Ram Kochhar to be Captain.

Temp. Lieut. J. Portelli to be temporary Captain.

The King has approved the retirement of Major F. O'D Fawcett and the resignation of Capt. Prabodh Chandra Roy

JOHANNESBURG MEDICAL SCHOOL.—On Jan. 28t the Governor-General of the Union of South Africa laid th foundation-stone of the Medical School of Johannesbur Mr. G. B. Steer, M.P.C., the Mayor, presided at the lunch tha followed, and proposed the health of the Governor-Genera Lord Buxton, in responding, remarked that his grandfathe was in his day a distinguished physician, and that he (H Excellency) had often wished that he had been allowed adopt the profession. He thought it was time th Johannesburg had its own medical school, especially there were certain diseases peculiar to miners whic required study, diagnosis, and treatment. He did n think the people of Johannesburg suffered from sleepin sickness, but they did suffer from nerves and excitabilit Indeed, his experience of five and a half years in Sout Africa was that Johannesburg and the Reef were t storm-centres of the country. At the stone-laying cer mony Lieutenant-Colonel W. Dalrymple, acting chairma of the School of Mines, said it was hoped to provide clas rooms, and, if necessary, clinical lecture theatres, for t departments of anatomy, physiology, pharmacolog bacteriology, and pathology. Lord Buxton said that was glad to know that the medical school would be open o equal terms to men and women.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 3RD.

Fleet Surgeons' Pensions.

Sir CLEMENT KINLOCH-COOKE asked the First Lord of the Admiralty whether he was aware that some 25 surgeon-commanders (fleet surgeons) had been placed on the retired list after reaching the age of 55 or completing 30 years' service, and notwithstanding that many of them were called up in August, 1914, and served throughout the war, some as surgeon-captains, their retired pension was only 10 per cent. higher than the rate fixed for surgeon-commanders 40 years ago, and if he would consider the possibility of increasing the pensions of surgeon-commanders called up for service during the war, as has been done in the case of officers in other branches of the service.—Mr. LONG replied: A number of surgeon-commanders (fleet surgeons) who retired before the war on reaching the age of 55 or on completing 30 years' service were called up during the war and served in the rank they held on the retired list, whether surgeon-captain or surgeon-commander. The exact number could not, however, be ascertained without examining each case separately. While re-employed such officers received, in addition to the full pay and allowances of their rank, a bonus of 25 per cent. of their full pay in lieu of counting the additional time served towards increase of retired pay. Under these conditions of service they would not have been entitled to increase of retired pay, but in accordance with the general arrangement made in the case of retired officers who served in a service capacity during the war, their retired pay was re-assessed on the new scale at the rates applicable to their age and rank at the date they originally retired. In the majority of cases the rate of retired pay was thus raised from £547 10*s.* to £600 per annum. The procedure adopted in re-assessing the rates of retired pay of surgeon-commanders called up for service in the war has been exactly the same as that adopted in the case of officers in other branches called up for service. It is true that the increase of retired pay is proportionately not so great in the case of the surgeon-commanders in question as in the case of certain other ranks, but some dissimilarity in this respect is inherent in any scheme which is framed to put the different branches of the Naval Service as far as possible on the same basis.

The Future of Poor-law Infirmaries.

Lieutenant-Colonel FREMANTLE asked the Minister of Health if he was aware that the present uncertainty as to the future utilisation of existing Poor-law infirmaries was hampering boards of guardians in their endeavours to make adequate provision for the needs of the sick either by way of extension or improvement of their institutions; whether, in the interests of an early reorganisation of health services, he would inform boards of guardians what was the policy of the Ministry with regard to these particular institutions and the use to which they were destined to be put under the new scheme of health services which was contemplated; and whether he was aware that the various health authorities in London and boards of guardians were particularly handicapped in making proper institutional provision for tuberculous persons owing to the failure of the Ministry as yet to carry into effect the declared policy of the Government with regard to the Poor-law.—Dr. ADDISON replied: Yes, Sir; but the matters referred to by the honourable Member involve questions of local government and other subjects of the first importance that can be dealt with only by legislation; and it is obviously necessary that I should lay proposals before Parliament and obtain its sanction thereto before I could properly adopt towards local bodies the attitude suggested in the question.

National Physique and Housing.

Mr. GRATTAN DOYLE asked the Minister of Health if his attention had been called to the report of the National Service Medical Boards regarding the defective physique of great numbers of men who were examined for military service; what action he proposed to take to improve the health and physique of the nation; and, seeing that the shortage of proper housing accommodation was one of the most serious contributing causes, what progress had been made during the last three months to deal with such shortage.—Dr. ADDISON replied: Yes, Sir; but it is quite impossible to set out within the limits of a reply to a Parliamentary question that very large variety of ways in which the causes and the treatment of disease are to be dealt with. In reply to the concluding paragraph of the question I may say that the number of houses for which the acceptance of tenders has been approved has increased during the last three months from about 12,000 to about 60,000.

Poor-law Infirmaries and Voluntary Hospitals.

Mr. BRIANT asked the Minister of Health if he would take steps to coördinate the work of the Poor-law infirmaries and voluntary hospitals so that persons requiring treatment should be sent direct to the most suitable institution, and should thus be saved the delay and danger of seeking admission at two or more institutions before obtaining the necessary treatment.—Dr. ADDISON replied: I am aware of the case which the honourable Member has in mind, and I will consider the question; but I have no jurisdiction over voluntary hospitals.

Mr. BRIANT: Does the right honourable gentleman not realise that no effective medical administration in the country can be obtained if he does not draw a distinction between Poor-law infirmaries and hospitals?—Dr. ADDISON: I am not quite sure that any effective administration would maintain that distinction.

Mr. BRIANT: Will the right honourable gentleman introduce legislation to make it effective?—Dr. ADDISON: Nobody is better acquainted with the complications of this subject than my honourable friend.

Middle Classes and Sickness Treatment.

Colonel NEWMAN asked the Minister of Health whether he was aware that, owing to heavy taxation and the increase in the cost of living, large numbers of the middle classes were unable to afford the expense of treatment and nursing in their own homes should illness overtake them; whether he was aware that they were unable and unwilling to obtain admission to and further overcrowd the large hospitals maintained by voluntary contribution for the pre-war poorer classes of the community; and what action did he propose to take to meet their necessities.—Dr. ADDISON replied: I am fully aware of the present pressure upon the voluntary hospitals, and the general question of the provision of hospital treatment has for some time past been engaging the attention of the Medical Consultative Council, from whom I am expecting a report shortly. I am not yet in a position to make any statement.

The Capital Value of Panel Practices.

Major PRESCOTT asked the Minister of Health whether he was aware that when the Regulations 16/1/C of the Government Insurance Act came into operation medical panel practitioners would be deprived of the advantage of the capital value of their practices; whether he was aware that a promise was given in 1913 to the effect that such an interest would be assured to the medical practitioner; whether he was aware that panel practitioners were apprehensive of the effect of these regulations upon the disposal of their practices; and if he would take into consideration the expediency of reviewing the situation.—Dr. ADDISON replied: I am not aware that any promise has been given in 1913, or indeed at any time, of the character indicated in the question. I am aware that some insurance practitioners are apprehensive—unnecessarily so—of the effect of the regulations referred to, and I am sending my honourable friend a copy of a reply which I have caused to be addressed to representations made to me on the subject on behalf of the Conference of Panel Committees.

THURSDAY, MARCH 4TH.

Salaries of Pensions Medical Officers.

Captain LOSEBY asked the Pensions Minister if the salaries of medical officers attached to the Ministry of Pensions hospitals were in some cases much in arrears; and if there was any reason why they should not be paid up to date.—Sir L. WORTHINGTON-EVANS replied: I have made inquiries, and am informed that the salaries of all medical officers who have been duly appointed to the staff of the Ministry are punctually paid at the end of each month. In some cases there has been delay in the formal appointment of medical officers who have taken up duty in advance of appointment and are thus left temporarily without pay. I am inquiring into this.

Dora Restrictions and Dublin Medical Services.

Captain REDMOND asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the recent Order under the Defence of the Realm Act in Dublin, whereby citizens were prohibited from being out of doors between 11.30 P.M. and 5 A.M., was inflicting serious hardship on the population, especially the poorer section in cases requiring medical and hospital attention; whether the nurses in many of the Dublin hospitals had declined to attend calls, and, as a consequence, maternity and other hospital cases were without the services of nurses and medical practitioners; and whether, in view of the grave consequences to which innocent and suffering people were being subjected, he was prepared to take steps to suspend the Order.—Mr. MACPHERSON replied: No complaints have reached me in this matter. From inquiry at the Dublin hospitals I have ascertained that in no case has there been a refusal to send out nurses in maternity cases. In two cases (Coombe Hospital) where nurses (permits not yet having been obtained) were required during prohibited hours the police escorted the nurses to their destination. The hospital authorities have since applied for permits for doctors and nurses. I believe, as a result of the inquiries made at hospitals, that the new regulations are rather welcome than otherwise to the staffs. There is a greater sense of protection when called out at night, and the only real inconvenience is that caused by the action of the corporation in extinguishing the street lamps at 11.30 P.M., thus leaving the city in complete darkness at night.

Captain REDMOND: Is the right honourable gentleman not aware that the matrons of all the principal hospitals in Dublin, including the Maternity Hospital in Holles-street and the Coombe Hospital, have stated publicly through the press that they will refuse to allow any of their nurses out between 12 midnight and 5 A.M.?—Mr. MACPHERSON: I cannot add anything to the answer I have given, one short sentence of which says: "The hospital authorities have since applied for permits for doctors and nurses."

Captain REDMOND: Is it not a fact that some poor women in a very advanced stage of pregnancy were not able to reach the hospital owing to these iniquitous restrictions?—Mr. MACPHERSON: I am not aware of that. I am convinced of this, that in cases of that kind the Government would be prepared to do everything to assist.

Reorganisation of Local Health Services.

Major HILLS asked the Minister of Health whether, now that his Ministry was in working order, he intended to suggest any, and what, steps to reorganise the local health services.—Dr. ADDISON replied: Yes, Sir; the matter is engaging my earnest attention, but I am expecting to receive shortly the recommendations of the Statutory Consultative Council on Medical and Allied Services, which I have undertaken to publish when available, and which must, of course, be carefully considered before the steps referred to in the question are decided upon.

Small-pox.

Sir A. YEO asked the Minister of Health if his attention had been called to a very serious state of affairs in connexion with the ex-Government stores being dumped at Bell Wharf, Bromley-by-Bow, E., and the reported death of one woman working in the wharf, and the isolation of five other persons from the same place, one of whom was in the service of the medical officer of health of the Poplar council, and what steps he proposed to take, if any, to rid the neighbourhood of the cause of the outbreak, as the matter was causing much alarm to the inhabitants.—Dr. ADDISON replied: Yes, Sir; I am aware of this case, and the Ministry in conjunction with the sanitary authorities has been taking active steps for some time past in endeavouring to check the spread of infection from the different centres to which it has been traced from the source indicated amongst, I regret to say, a population largely unvaccinated.

Sir A. YEO: Will the right honourable gentleman take steps to have this dump burned in order that the disease may be stamped out? Otherwise there will be more outbreaks and more serious trouble for the Health Department.—Dr. ADDISON: The value of the stores dumped is about a quarter of a million. The small-pox has now spread to various other places in the district, so that burning the dump would not remove the danger.

Sir A. YEO: Is not the life of this poor woman worth more than a quarter of a million pounds?—Dr. ADDISON: It would not restore the woman to life to burn the dump.

Sir A. YEO: But it would save others from being buried.

Decisions on Second Pensions Report.

In reply to Captain COOTE and Sir M. BARLOW, Sir L. WORTHINGTON-EVANS stated that the Government had decided to accept the majority of the 49 recommendations made in the Second Report of the Select Committee on Pensions. In particular it had been found possible to accept the whole of the recommendations as to the disability scales of pay of regular and temporary officers. The recommendations with regard to officers' widows' pensions, the pensions and allowances in respect of children, and the loading up of pre-war earnings for the assessment of alternative pensions had also been accepted with slight modifications. With regard to the recommendations concerning the dependents of non-commissioned officers and other ranks the Government had accepted the proposals to increase the limits of pre-war dependents' pension and the special need pension to 20s. a week, and were prepared to give the Special Grants Committee discretion to deal with certain cases of special hardship, as recommended by the Select Committee. The Government were, however, unable to accept the Committee's recommendation that all pre-war dependency and special need pensions should be scaled up by an extra 13 per cent., but hard cases would be met partly by a revision of the existing need scale and partly by the Special Grants Committee. The estimated cost of the recommendations made by the Committee, including the continuance of the 20 per cent. bonus was £3,000,000. The estimated cost of the improvements accepted by the Government was £1,900,000. The work of re-assessment woul be carried out as rapidly as possible, and payment woul be made as from April 1st, with arrears from that date. In a detailed statement which the right honourable gentlema circulated later it is announced that the suggeste increases for matrons and nurses are approved. In regar to nurses' dependents the proposals made to the Treasur by the Ministry of Pensions on behalf of the Special Grant Committee had now been sanctioned. Most civilian nurse were already dealt with under the dispensing warrant, but i existing powers were found to be insufficient further consideration would be given to cases of hardship. The Genera Service Section V.A.D. were not nurses, but women engage on ancillary duties. The question whether compensatio could be provided for them would be considered by th War Office.

MONDAY, MARCH 8TH.

Insurance Practitioners' Remuneration.

In reply to a question from Sir PHILIP MAGNUS, th MINISTER OF HEALTH stated the result of the arbitratio in respect of medical men working under the Nationa Insurance Act, which has already been published in th press (see p. 615 of this issue of THE LANCET), adding, "th utmost goodwill exists on both sides and a sincere appreciation of the impartiality and service of the arbitrators." To further question, inquiring the cost to the Exchequer, Dr ADDISON answered that these details would be supplied i connexion with the National Health Insurance Bill shortl to be introduced.

Ireland and the Insurance Bill.

Captain REDMOND asked the Minister of Health if h would state whether the National Health Insurance Amendment Bill was to be applied to Ireland.—Dr. ADDISO replied: The answer is in the affirmative.

Medical Treatment of Children.

Sir CYRIL COBB asked the Minister of Health whethe it had been found in practice that the duty imposed unde Section 1 of the Local Education Authorities (Medical Treatment) Act, 1909, of recovering a charge for treatmen deterred parents from obtaining such treatment for thei children; whether he was aware that in certain areas th Act had become a dead letter; whether, in view of this fac it was the intention to amend or repeal the Act; and, if i was not the intention to amend or repeal the Act at an earl date, what action should be taken by an authority whic was anxious to comply with the section but found that th making of any charge which would justify the cost o collection had a tendency to deter parents from obtaining th necessary treatment for their children.—Dr. ADDISO replied: I have received no representations of the natur referred to in the first part of the question; in any case an amendment affecting the principle of the Act could onl properly be considered in close connexion with the genera question of the organisation of public health services, o which, as I have before indicated, I am not yet in a positio to make any statement.

Medical Examination of Teachers.

Lieutenant-Colonel HURST asked the President of th Board of Education whether he would consider the expediency of relieving teachers who enlisted in the army a A 1 men and received wounds on service from medica examination and from having to pay a fee for such examination, in order to place them at no disadvantage to non-serving teachers in respect of the death gratuity under th School Teachers (Superannuation) Act, 1918.—Mr. H. LEWI (Parliamentary Secretary to the Board of Education) replie My right honourable friend is afraid that he is debarre from adopting the honourable Member's suggestion by th provisions of Section 3 (1) of the Act. Teachers who serve with the forces are not in a position different from that other teachers as regards medical examination and th payment of the fee for such examination.

TUESDAY, MARCH 9TH.

Hospitals for Uncertifiable Mental Cases.

Mr. LAWSON asked the Secretary for War if he would stat how many houses or hospitals were provided under h department for uncertifiable cases of loss of mental balanc occurring among soldiers; where these houses were situate what was the accommodation in each; and whether it wa still the policy of the War Office to retain these cases of nerv strain under military control in so-called war hospita staffed by lunacy officials and lunacy attendants.—M CHURCHILL replied: I assume the honourable Member referring to accommodation for cases of mental disorde Soldiers suffering from nerve strain are not sent to wa (mental) hospitals unless the conditions of the patient constitutes actual mental disorder, but are treated in neurologic hospitals or neurological sections of general hospitals. The is one hospital for cases of mental disorder, viz., Lord Derby's War Hospital at Winwick, Warrington. There are 1000 beds in the hospital and the number of patients at present is 741. It is still the policy to retain such cases in the hospital until they are cured, if this seems likely to occur. Otherwise they are discharged to the care of their friends or to appropriate institutions.

Deafness through Shell Shock.

Mr. HOUSTON asked the Secretary for War whether he could state the number of soldiers who during the war had become totally deaf through shell shock or other causes; and whether institutions would be provided for these men to be taught lip-reading and useful occupations on the lines of St. Dunstan's Hospital for the Blind, so that they might be enabled to earn their livelihood.—Sir L. WORTHINGTON-EVANS replied: The number of the totally deaf cannot be stated, but approximately 30,000 men have been pensioned for deafness of greater or less degree. Medical boards are instructed to recommend a course of tuition in lip-reading where the degree of deafness is such as to render this desirable. Lip-reading classes are held in London at the Ministry's aural clinic (28, Park-crescent, Regent's Park) and at 30 other centres throughout the country.

Sanatoriums for Nerve Strain.

Mr. LAWSON asked the Pensions Minister if he would state how many houses or sanatoriums were provided under his department for ex-soldiers disabled through nerve strain, but whose loss of mental balance was not such as to necessitate certification; and whether he would take steps to secure that, for the cheer and encouragement of such patients, the voluntary houses which were so greatly needed should be kept wholly apart from lunacy administration and unconnected with the Lunacy Board.—Sir L. WORTHINGTON-EVANS replied: There are 12 special institutions with accommodation for nearly 1500 patients available for the treatment of neurasthenic cases. A considerable number of beds are also reserved for such cases at other Ministry hospitals. These institutions are all under the direct control of this Ministry and are unconnected with lunacy administration.

Captain REDMOND: Are there any of these institutions in Ireland?—Sir L. WORTHINGTON-EVANS: As my honourable and gallant friend knows the Irish law on the subject is not the same as here. We have got the Ministry institutions in Ireland, although I think the accommodation is not sufficient.

Protective Health Services.

On a Supplementary Estimate in Committee of Supply of £100 for the Ministry of Health, Dr. ADDISON, Minister of Health, explained to the Committee what he described as the "protective" services which came under the jurisdiction of his department. There was £100 for grants to port and riparian sanitary authorities, which was required for the improvement and extension of the machinery to prevent the importation into this country of any of the diseases which were ravaging other parts of the world. His aim was to erect a protective screen round this country, and he had no doubt that this £100 for which he was asking would in the course of the next few years grow into thousands of pounds. The additional sum required for child welfare was £130,000. They had opened 400 new child welfare centres this year. Midwifery services required great development, but they had during the past year supplied these services for a population of 200,000. They had, however, gone nothing like far enough yet. They had also made progress in the provision of maternity homes, which were badly needed all over the country. During the past year they had established 50 of these homes, and it was the intention of the Department to go on establishing more. The infant mortality rate of last year was the lowest on record. It had now reached 89 per 1000. But it ought to be brought down to 50. The improvement nevertheless was significant. The estimated saving (amounting to £815,090) was not due to bad estimating, but to the fact that on the whole there had been better health among insured persons, which he attributed to better wages and employment. In the main that reflected an improved national health, and if they got an improved service by the aid of the referees he sincerely hoped that they would see a better figure next year. The estimate was agreed to.

Dr. E. Colston Williams, the newly appointed medical officer of health for Glamorgan, recently opened an interesting discussion at a branch meeting of the Society of Medical Officers of Health upon the Working of the Mental Deficiency Act and School Work. He advocated neighbouring authorities combining in order to provide economically the needed institutions. His suggestion received strong support, and a resolution was passed to advise that no premature steps be taken by local authorities before the whole needs of the Principality are ascertained and carefully considered.

Medical News.

MEDICAL RECORDS UNDER NATIONAL HEALTH INSURANCE.—The Minister of Health and the Scottish Board of Health have appointed an Inter-Departmental Committee to consider and advise them as to the form of medical record to be prescribed under the conditions of service for medical practitioners contained in the new Medical Benefit Regulations, having due regard to the clinical purposes (including the remedial value to the patient of maintaining a suitable record of his case), as well as to the administrative and the statistical purposes which such records may be adapted to serve. The Committee consists of the following members:—

Sir Humphry Davy Rolleston, K.C.B., M.D., F.R.C.P. (Chairman),
Emeritus Physician, St. George's Hospital; President, Royal Society of Medicine.
H. B. Brackenbury, M.R.C.S., L.R.C.P.,
Chairman, Insurance Acts Committee.
J. Brownlee, M.D.,
Director of Statistics, Medical Research Committee.
H. G. Dain, M.B.,
Chairman, Birmingham Insurance Committee.
J. R. Drever, M.B.,
Scottish Medical Secretary, British Medical Association.
J. Crauford Dunlop, M.D.,
Superintendent of Statistics, General Register House, Edinburgh.
C. E. S. Flemming, M.R.C.S., L.R.C.P.,
Member, Wiltshire Insurance Committee.
A. Fulton, M.B.,
Vice-Chairman, Nottingham Insurance Committee.
M. Greenwood, M.R.C.S., L.R.C.P.,
Medical Officer (Medical Statistics), Ministry of Health.
R. W. Harris,
Assistant Secretary, Ministry of Health.
H. W. Kaye, M.D.,
Director of Medical Services, Ministry of Pensions.
J. C. McVail, M.D.,
Scottish Board of Health.
H. Meredith Richards, M.D.,
Welsh Board of Health.
T. H. C. Stevenson, C.B.E., M.D.,
Superintendent of Statistics, General Register Office.
S. P. Vivian,
Deputy Registrar-General.
J. Smith Whitaker, M.R.C.S., L.R.C.P.,
Senior Medical Officer, Ministry of Health.

The joint secretaries of the Committee are G. F. McCleary, M.D., and A. E. Joll, of the Ministry of Health, Whitehall, S.W. 1.

Queen Alexandra will unveil the Nurse Cavell Memorial on Wednesday, March 17th.

Dr. J. C. McWalter has been appointed High Sheriff of Dublin.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting, held on March 1st, the following were admitted (after examinations) as Fellows: Dr. Andrew Allison (Ibrox), Dr. Thomas Blackadder Gilchrist (Johannesburg), Dr. John Clark Middleton (Glasgow), and Dr. Robert Cecil Robertson (London). At the same meeting Dr. Thomas Forrest, of Glasgow, presented to the Royal Faculty a case of surgical instruments which had been the property of and were used by the late Lord Lister while he was a surgeon in the Glasgow Royal Infirmary. Dr. A. Freeland Fergus, President, on behalf of the Fellows, accepted the gift with very great pleasure, and stated that it would be placed in the archives of the Faculty.

UNIVERSITY OF WALES: MEDICAL FACULTY.—The suggestion has been made that in future the King Edward VII. Hospital, Cardiff, should become (1) a centre for clinics, venereal, psychiatric, tuberculosis, school, maternity and child welfare, in addition to ordinary out-patient work; and (2) a clearing station, its beds being devoted to urgent and major cases. Another hospital situated outside the town—on a site known as the Rookwood Estate at Llandaff—it is proposed, should accommodate cases passed on to it and also simple and ordinary medical and surgical cases. Much is to be said for this plan, which, it is thought, would appeal to the Welsh Ministry of Health, who desire each general practitioner to have access to a medical institute. Under this scheme the major beds in the centre would be served by the consultants, while the outside hospital would become a medical institute. Further, this plan would allow for almost indefinite expansion in the future, as Rookwood is a beautiful estate comprising some 30 acres excellently placed for fresh air and sunshine.

The Osler Memorial.—A distinguished gathering met at the University Museum, Oxford, on March 6th to decide on the form of a memorial to the late Regius professor of medicine. Three resolutions were proposed and approved. The first, by Sir Clifford Allbutt, that the distinguished services of the late Sir William Osler were deserving of a permanent memorial in Oxford. The second, by Sir William Church, that the most appropriate form of memorial would be an Osler Institute of General Pathology and Preventive Medicine. The third, by the Dean of Christ Church, to appoint a committee and issue an appeal for funds. Professor J. A. Gunn intimated that a provisional committee, consisting of Professor W. H. Welch (Baltimore), Professor Harvey Cushing (Boston), Professor F. Billings (Chicago), President G. R. Butler and Professor Walter B. James (New York), was coöperating in America, and a similar arrangement in Canada was contemplated.

No. 3 Casualty Clearing Station.—With reference to the announcement in The Lancet of Feb. 28th the first reunion dinner will take place at Jules's Hotel, Jermyn-street, London, W., on Saturday, March 20th, at 7.30 P.M.

No. 5 General Hospital, London.—It is proposed to hold a reunion dinner of officers who were attached to No. 5 General Hospital, B.E.F., in London on Saturday, April 10th. Those who wish to attend are asked to write to Dr. G. T. Loughborough, 3, Lexham-gardens, Kensington, W. 8.

London (Royal Free Hospital) School of Medicine for Women: Annual Dinner.—The annual dinner of past and present students and friends of the school, now revived after the war period, is being held to-day (Friday) at the Abercorn Rooms, Liverpool-street, at 7 for 7.30 P.M.

Great Northern Central Hospital.—A successful drawing-room meeting was held by Mrs. Perronet Sells at "Beechwood," Hampstead Lane, Highgate, on March 8th in connexion with the Ladies Association of the Great Northern Hospital. In response to an appeal for new members 38 ladies joined the association, and the sum collected for the hospital among the guests amounted to £32 8*s.* 6*d.*

Chelsea Clinical Society.—A meeting of this society, which has now resumed its activities, will be held on Tuesday, March 16th, in St. George's Hospital Medical School, at 8.30 P.M., when a discussion will be opened by Dr. D. M. Barcroft on "Is Asthma a Disease of the Chest?" Sir Thomas Horder, Dr. Leonard Williams, and Dr. Hernaman Johnson are expected to continue the discussion.

Venereal Prevention in Portsmouth.—After considering a special report on the prevention of venereal diseases drawn up by the medical officer of health, Dr. A. Mearns Fraser, the Portsmouth health and housing committee passed a resolution urging the council—

> "to empower the committee at once to take the necessary steps to disseminate a knowledge of the methods of prevention indicated in the report among the male population of the borough, and to impress upon men their duty to the community in this matter."

Leeds and West Riding Medico-Chirurgical Society.—At the last pathological meeting of this society, held at the Medical School, Leeds, a large number of specimens were exhibited and the following papers read:—Dr. W. MacAdam: The Practical Application of the Newer Methods of Chemical Analysis to Clinical Medicine. An account was given of recent advances in the methods of physiological chemistry, especially in connexion with blood and urine analysis. The lines along which estimation of the sugar content of the blood may assist diagnosis and treatment of the various types of glycosuria were indicated, whilst the additional information thus gained, as compared with that obtained from urinary examinations alone, was discussed. The newer tests for the estimation of renal function were described, an account being given of the findings obtained from estimations of the urea content of the blood, considered along with McLean's urea-concentration test, in various medical and surgical conditions of the kidneys.—Dr. J. W. McLeod: A Suggested Criterion of Virulence amongst Streptococci. After dealing with the differences of opinion which have arisen as to the relation which hæmolytic power bears to the virulence of streptococci, Dr. McLeod pointed out that experiments on rabbits show that the power of streptococci to produce hæmolytic toxin, when grown on undiluted rabbit serum as a culture medium, is closely related to their virulence for rabbits. Adopting the same criterion with human serum, it has been found that a small number of strains can be distinguished as presumably of high virulence. The two strains which were indicated by this criterion as most virulent both came from cases of acute streptococcal meningitis.

Bideford (Devon) Hospital.—It has been decided to make extensions and improvements at the Bideford Hospital at an estimated cost of £4000. £1300 have already been promised, and the committee thinks that the requisite amount will be raised.

Tavistock (Devon) Hospital.—At the annual meeting of the friends of this institution, held on Feb. 25th, it was decided that all medical practitioners within the area of the Tavistock union should, when possible, attend their own patients when resident in the hospital.

Exeter Dispensary.—The annual meeting of the subscribers to this institution was held on Feb. 25th. The medical report stated that 2213 patients had been treated during the year. It was reported that the charity was having an adverse balance of about £500 every year. Dr. T. R. C. Whipham was elected honorary physician, and Dr. J. S. Steele-Perkins and Dr. G. P. D. Hawker were elected on to the honorary consulting staff.

University of Bristol.—The following candidates have passed the Third Examination for the Diploma in Dental Surgery: Norman Harry Bodenham and Kenneth George Hyland.

Bristol Medical Mission.—At the annual meeting of the subscribers to this institution, held last week, it was reported that during the past year 3596 patients had been treated. The income was £1137 and there remained a favourable balance of £65.

The Voluntary Hospitals of Bristol.—The movement towards union between the voluntary hospitals of Bristol is developing. An apparently authoritative summary in the local press has stated that a council of all the hospitals would be set up on a basis of proportional representation, to include also representatives of the University Council and of the honorary staffs. A financial amalgamation is also proposed. The wishes of past benefactors will in all cases be respected, and the house committees of the several hospitals will continue to act as at present. At the annual meeting of the General Hospital, on March 8th, the chairman of committee, Mr. Herbert M. Baker, said that these proposals were still under discussion by the committee set up to consider the whole situation, and that if they were approved by that committee they would then be referred to each of the hospitals concerned for consideration and report. Mr. George A. Mills, the President of the hospital, spoke in favour of the principle of coöperation between hospitals, and suggested to the Lord Mayor, who was in the chair, the suitability of a fund for extinction of debt, and provision of endowment of the hospitals as a war memorial for Bristol. That indefinite delay in the decision as to amalgamation is undesirable is suggested by a remark of Mr. William Garnett, when presiding at the meeting of the Children's Hospital on March 2nd, to the effect that building schemes for a new out-patient department, a nurses' home, and a block for the treatment of surgical tuberculosis had been postponed pending a settlement of the proposals for amalgamation. It is presumably on account of the impossibility of waiting long for the provision of these and other premises that a time-limit is suggested. Each hospital is to be asked to arrive at a decision on its attitude toward a policy of union before May 31st.

Hospitals and Paying Patients.—"One other need of the future—nay, rather of the immediate present—should be mentioned, and that is provision for the reception of patients able to contribute towards the cost of their treatment." This is an excerpt from the report presented at the annual Court of Governors of the Royal Sussex County Hospital at Brighton on Feb. 25th, and created a discussion tending to show that the governors consider the course a wise one to pursue. No actual resolution was submitted, but Mr. Scrase Dickins said the class they used to regard as the sick poor were now in many respects the most well-to-do of the community, while others who hitherto were in a superior position found it almost impossible to make both ends meet, and in time of sickness were in exceptionally unfortunate circumstances. The poorest were provided for, but there was no provision for the intermediate class, and it was very difficult for the board to decide who should be admitted as patients. Another speaker, in voicing entire sympathy with the suggestion, expressed himself in this way—that there was no "half-way house" for the people of Brighton and Hove. From the annual report it was gathered that the normal number of beds (202) had been increased temporarily to 218 in order to cope with the number of patients, the in-patients numbering 2956. Out-patients totalled 5561, and 4189 casualties were treated. The total income for the year was £23,188 3*s.* 3*d.*, and the expenditure £28,608 11*s.* 2*d.*, leaving a deficit of £5420 7*s.* 11*d.*

The annual general meeting of governors of the Royal Dental Hospital of London, Leicester-square, will be held at the hospital on Thursday, March 25th, at 5 P.M.

Hospital Conditions in Liverpool.—It was recently pointed out in Liverpool that the upkeep of the hospitals must no longer be considered a matter of charitable benevolence, but the duty of all who participate in their benefits. Directly or indirectly every member of the community does participate in these benefits, but a study of available local subscription lists show that only a very small proportion of the beneficiaries lend their aid.

Liverpool Royal Infirmary.—The 171st annual meeting of the governors of the infirmary was held on March 5th. Alderman Crosthwaite, the retiring President, in submitting the annual report, mentioned the fact that in 1846, during the presidency of his father, the remark was made that "the advance in the price of articles of food had added considerably to the expenses of the institution." The same might be said with added force of the present situation. During 1919 the in-patients numbered 4618 and the out-patients 32,138. It was proposed to add an out-patients' clinic to the School of Tropical Medicine, which recorded 35,795 attendances last year, while the massage department in connexion with orthopædics had 41,858. He made a special appeal that all in receipt of higher wages should assist the committee in raising funds for the increased salaries of the nurses, which were now equal to the standard recommended by the College of Nursing. The honorary treasurer, in submitting the accounts, pointed out that but for a timely and anonymous donation of £20,000, received last December, the committee would have been placed in serious financial difficulties. There was still an adverse balance of £4712. Mr. H. Wade Deacon saw hope for the financial future of such institutions in the fact that the British Red Cross and St. John Association had resolved to transfer their money-raising energies from war to peace. The suggestion recently made in London of charging hospital patients 10*s.* weekly for food would require serious consideration before adoption in the provinces. He believed that the usefulness and economy of hospitals could be increased by a system of coördination under which acute cases would not be kept in a fully equipped hospital nearly so long after operations as at present, but would soon be removed to a supplemental hospital and thence to a convalescent home if necessary. The report and accounts were adopted, and Dr. Richard Caton, whose association with the infirmary dates from 1886, was elected President.

Royal Southern Hospital.—Under the presidency of the Lord Mayor the annual meeting of this institution was held on March 8th. The seventy-eighth annual report for 1919 showed the number of in-patients to have been 2340, as compared with 2176 in 1918, while the out-patients numbered 15,880 with 70,593 attendances, as compared with 14,905 and 61,213 respectively. All the special departments have been fully utilised and the attendances have increased considerably. In the venereal diseases department the number of in-patients treated during the year was: males 66, females 140. New V.D. out-patients numbered: males 305, females 115, and the total attendances were 1229 males and 940 females. The ordinary expenditure amounted to £29,952, an increase of £3033. The ordinary income fell far short of the needs, but during the year a large amount of extraordinary income amounting to £20,707, of which £13,335 was due to legacies and £3550 to special donations, had come to hand and had relieved the financial strain. A debt of £4488 is still owing to the bank and other creditors. With a view to shortening the hours of duty of the nursing staff the committee has decided to extend the nurses' home to give accommodation to 21 additional nurses. The new building, costing approximately £8500, is now approaching completion. The salaries of the nurses have also been revised and raised to a standard equal to the average paid throughout the country. Together with its annual report the committee is issuing a special appeal which embodies many interesting facts. Whereas in 1910 the ordinary income was £9918, and the ordinary expenditure £12,462, the income in 1919 (less the sum paid by Government in respect of the treatment of wounded and disabled soldiers and sailors) was £14,026, and the expenditure £29,952. Although the cost of commodities, maintenance, and so forth has risen by £17,489, the additional amount subscribed towards this increase has been only £4107. The committee is desirous of bringing these facts home to every wage-earner and employer. The £46,000 raised by the Lord Mayor's appeal in Liverpool compares very unfavourably with the amount raised in other cities in response to similar appeals. Cardiff has raised close on £95,000, and Leeds, by its employers' contributory scheme, is anticipating an additional £25,000 per annum for hospital maintenance. The names of the makers of war fortunes find their way but slowly into the subscription lists, and the working man, although his wages have increased, has not proportionately increased his donations.

National Hospital for the Paralysed and Epileptic, Queen-square.—The annual general meeting of governors will be held at the hospital on Tuesday, March 23rd, at 4.30 P.M.

Plague on a Japanese Liner.—The Ministry of Health announces that the case of plague occurring on the s.s. *Alps Maru* in the Port of London, announced on Feb. 19th, was followed by a further fatal case among the crew whilst the vessel was in the port. The patient was removed to the Port Sanitary Authority's isolation hospital on March 4th, and died there the next day. The portion of the cargo destined for London was discharged into lighters and barges, and the necessary precautions are being taken concerning it. The ship was disinfected as far as practicable, but the holds which still contained cargo could not be dealt with. The vessel left the Port of London on March 6th.

The People's League of Health.—In connexion with the league the Lord Mayor of London will preside at a meeting of provincial mayors to be held at the Mansion House on May 11th, when members of the medical council of the league will urge on all the boroughs and counties the duty to take up the task of raising the general health standard and lessening the deplorable mortality from preventable disease.

Influenza in Zurich.—A sharp epidemic of influenza occurred in Zurich (population 210,000) in February, the total number of cases medically reported between Jan. 18th and Feb. 28th being 11,864. Probably an equal number remained unreported; 2210 of the notifications referred to children. The deaths numbered 166, mostly ascribed to pneumonia. An epidemic of meningitis lethargica coincided with that of influenza: 51 cases with 18 deaths, a high case-mortality. The epidemic is now (March 7th) rapidly declining.

Financial Condition of Norfolk Hospitals.—There is a distressing monotony about the annual reports of many Norfolk hospitals now being published. In all cases the expenses have vastly increased, with no corresponding increase of subscriptions and donations. The artisan classes who have made so much money during the war do not seem yet to have recognised their obligations towards the hospitals, and the ordinary subscribers have not, as a rule, increased their contributions to make up for the falling value of money. The Jenny Lind Hospital for Children in Norwich has to face this year a deficit of £2054 15*s.* 4*d.* The committee is also asking for a sum of about £6000 to provide further accommodation for its nursing staff, which will have to be increased owing to the curtailment of working hours. During 1919 the number of patients admitted to this hospital was 868, the daily average number of beds occupied was 54·8, and the number of operations 443. In the out-patient department the number of new patients was 2464, the number of attendances 13,461, and the number of operations 355. An X ray and electrical massage department has been opened within the last few months and Dr. A. J. Cleveland has been appointed physician in charge.

Another Norfolk hospital appealing for funds is the West Norfolk and Lynn Hospital, King's Lynn. Last year the expenditure exceeded the receipts by about £1200, and the board pointed out that, as each in-patient cost as a rule £9, the present rate of subscription was hopelessly inadequate; an appeal was made to all residents in the area served by the hospital to increase their contributions in proportion to the increased cost of commodities and of all forms of labour. The number of in-patients treated in the hospital in 1919 was 575; out-patients, 266; dental cases, 162; casualties, 763; operations, 439; and deaths, 48. There was a considerable increase in the number of in-patients and operations over the preceding year, but a diminished number of out-patients. The hospital board considered that to make the hospital efficient and up to date three distinct improvements were absolutely necessary—viz.: (1) a nurses' home; (2) an out-patient department equipped on modern lines; and (3) a self-contained laundry. It was resolved, at a special meeting of the governors held on May 13th, 1919, that a salaried surgical specialist should be appointed to be responsible for all the surgical work of the hospital. This appointment was offered to Mr. C. E. S. Jackson, who took up his new duties on Oct. 1st. Mr. C. T. M. Plowright was appointed honorary consulting surgeon, and Dr. J. R. Kingdon and Dr. W. B. Wedgwood continued to act as honorary physicians and Mr. S. A. T. Coxon as honorary dental surgeon. At the request of the Ministry of Pensions a clinic was organised in September for the treatment of men partially disabled in the war, and Miss Partridge was appointed masseuse. Forty men in all had received and benefited much by this treatment, and it was now found necessary to employ a second masseuse.

Appointments.

CARLILL, H., M.D., B.Ch. Cantab., has been appointed Physician to the Westminster Hospital.

FENTON, J., M.D., D.P.H., Medical Officer of Health for the Royal Borough of Kensington.

Certifying Surgeons under the Factory and Workshop Acts: ANGLIM, W. J., L.R.C.P. & S. Irel. (Duncannon); FOUNTAIN, E. D., M.R.C.S., L.R.C.P. Lond. (Great Wakering); COX, E. H., M.B., Ch.B. Vict. (Rochdale); MCKENNA, J. H., L.A.H. Dub. (Ballylynan); ROBERTSON, J. D. (Kidwelly); SHEEDY, T. (Aughrim).

Vacancies.

Wednesday, March 17th.—2 P.M., Dr. Yealland. 3.30 P.M., Dr. Collier: Aphasia and Apraxia. (I.)

Thursday, March 18th.—2-3.30 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Ward Cases: Dr. S. A. Kinnier Wilson.

Friday, March 19th.—2-3.30 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Dr. Gordon Holmes: Cerebellar Disease. Ataxia. (II).

Saturday, March 20th.—9 A.M., Surgical Operations.

Fee for Post-Graduate Course £7 7*s*. C. M. HINDS HOWELL, Dean.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Saturday, March 13th.—10 A.M., Dr. A. Saunders: Medical Diseases of Children.

Monday, March 15th.—5 P.M., Mr. D. Armour: Cervical Rib.

Tuesday.—5 P.M., Dr. Pritchard: Some Common Infections.

Wednesday.—5 P.M., Dr. Beddard: Practical Medicine.

Thursday.—5 P.M., Mr. Baldwin: Practical Surgery.

Friday.—5 P.M., Special Lecture:—Prof. Sir Clifford Allbutt: Kinds of Pneumonia.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

Wednesday, March 17th.—4.30 P.M., Dr. C. Wall: Bronchitis and Emphysema.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Tuesday, March 16th.—3 P.M., Prof. A. Keith: British Ethnology: The Invaders of England. (Lecture III.)

Thursday.—3 P.M., Mr. S. Graham: (1) The Spirit of America After the War.

Friday,—9 P.M., Mr. E. McCurdy: Leonardo da Vinci.

Saturday.—3 P.M., Prof. Sir J. J. Thomson, O.M.: Positive Rays. (Lecture V.)

CHADWICK PUBLIC LECTURES, in the Lecture Room, Royal Society of Arts, John-street, Adelphi, W.C.

Monday, March 15th.—5.15 P.M., Lecture:—General Sir John Goodwin, K.C.B., C.M.G., D.S.O.: Military Hygiene in Peace and War. II., Army Hygiene during the Recent War (Application of its Principles to Active Service Conditions). (Illustrated by lantern slides.)

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE DEMONSTRATIONS, at the Sheffield Royal Hospital.

Monday, March 15th.—3.30 P.M., Dr. Nutt: X Ray Therapeusis.

Tuesday.—4 P.M., Dr. Hay: Subjective Sight-testing.

Wednesday.—3.30 P.M., Dr. Wilkinson: Mastoid Suppuration.

Thursday.—3.30 P.M., Dr. Skinner: New Growths of Skin.

Friday.—4 P.M., Dr. Hay: Injuries of Cornea

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, March 16th.—4.30 P.M., Mr. P. R. Wrigley: Carcinoma of the Breast.

SALFORD ROYAL HOSPITAL AND ANCOATS HOSPITAL POST-GRADUATE DEMONSTRATIONS, at the two Hospitals alternately.

Thursday, March 18th.—4.30 P.M., Lecture:—Mr. Macalpine: Indications for Prostatectomy. (At the Salford Royal Hospital.)

BRIGHTON DIVISION OF THE BRITISH MEDICAL ASSOCIATION, at the Sussex County Hospital.

Thursday, March 18th.—4 P.M., Clinical Demonstration.

Notes, Short Comments, and Answers to Correspondents.

MILITARY HYGIENE IN OLDEN TIME.[1]

BY SIR JOHN GOODWIN,
DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.

HYGIENE is a science with which every army medical officer is intimately concerned, and I propose in my first lecture to endeavour to trace the history of army hygiene, more especially in war, and to show what an immense bearing hygiene has on the success or failure of an army in the field. The commander of a force naturally views with the gravest concern any depletion from sickness of his effective troops. One sick man does not merely imply the loss of one rifle; it entails the diversion of otherwise useful man-power into the services of hospitalisation and transport. Until quite recent years it has never been sufficiently recognised that a very large proportion of army medical effort should be directed towards the prevention of disease. It might be of interest to you if I reviewed briefly

History and Progress of Army and Civil Hygiene.

Some of the earliest sound and concise rulings for sanitation in an army on active service were recorded in Deuteronomy, which was probably written more than 2500 years ago. Moses insisted above all things that the camps must be kept clean. He gives detailed sanitary rules to be observed, especially regarding the disposal of excreta. In Xenophon's analysis, written 379–371 B.C. we read how silver kettles were carried with the army to provide boiled water for drinking purposes. Xenophon also, in describing the retreat of the Greeks, tells us that they were very liable to blindness—doubtless snow blindness—and also describes the mortification of the extremities from snow and cold. Pliny describes the disease which afflicted the Roman army in Germany and—a very interesting point—mentions how the Romans constantly shifted their camps in order to combat the evil; it is also interesting to read that Alexander the Great's main principle in the preservation of the health of his army over 2000 years ago was a very frequent change of encamping ground. As regards actual losses from sickness, Plutarch states that Demetrius in his last expedition lost over 8000 men from sickness, while at the siege of Syracuse the Carthaginians were almost destroyed by a pestilence attended with a flux of blood.

In the fourteenth century the "Black Death" was terribly fatal in its effects. Europe is supposed to have suffered losses to the extent of 40 millions and China 13 millions from this disease. 150 years later the "sweating sickness" was carried by Henry VII.'s army throughout this country, and was the cause of an extremely heavy mortality. In the sixteenth and seventeenth centuries several epidemics of plague occurred in England, and this disease is supposed to have been eradicated from London by the great fire in 1666.

Prevention of Disease.

Very little was, however, written as to the prevention of disease, and Sir John Pringle, in 1768, stated that when he joined the army there was little, if any, literature on the subject. The same writer, in describing the terrible outbreaks of dysentery in our army in Flanders in the years 1742–1745, stated that the disease usually supervened in the autumn, and was due, in his opinion, to the advent of the colder weather at night. He remarks the fact, as if it were a curious coincidence, that the health of the troops appeared immediately to improve when they were removed to a fresh area, and he hazards the opinion that possibly the foul straw and the privies may have been contributory causes. The chief remedies, he states, were the lancet and blisters.

Amongst all this chaff, this groping in the dark, we come across gleams of light, occasional grains of sound advice. The following sentence, written of the army more than 150 years ago, holds equally good to-day. "The preservatives from diseases are not to depend on medicines, but upon such orders as, at the same time that they do not appear unreasonable to him, the soldier shall be obliged to obey." Towards the close of the eighteenth century we begin to obtain something in the nature of figures regarding sickness of armies in the field. In 1792 the allied Austrian and Russian armies during one month, without any considerable fighting, lost 25,000 men, or more than one-fourth of their number, every village being filled with dead and dying. Sir John Pringle mentions, apparently as one of the advantages of a military life in the early part of last century, that "the soldier, in time of war, by the smallness of his pay, is secured against excess in eating, the most common error in diet."

Many army reforms were brought about by Sir James McGrigor, who became Director-General of the army in 1814. It was due to him that each soldier in barracks was provided with a separate bed; indeed, it was only a very short time before that an army medical officer, Dr. Robert Jackson, who must evidently have been a most troublesome fellow, introduced a system of dieting the sick while in hospital, and also insisted that sick soldiers should have separate beds instead of having to lie two or three together, as had formerly been the custom.

Mortality from Sickness in Various Campaigns.

Probably one of our most disastrous campaigns, from a hygienic point of view, was the Walcheren Expedition of 1809, where our mortality from disease amounted to 346·9 per 1000 of strength of troops. We have all read of the trials and hardships of the troops in the Crimean War in 1854 in which the mortality from disease amounted to 230 per 1000 of the strength. In the Afghanistan War of 1878–1880 the mortality was 93·7 per 1000, showing some improvement. Bad as these figures are, those of other nations are even more unfavourable; for example, in the French Soudanese Campaign of 1888–1889 the mortality from disease amounted to 280 per 1000, worse figures than those of our own army in the Crimean Campaign 35 years previously.

I think that perhaps the most striking example of the havoc which may be wrought by disease in an army in the field is that furnished by the French army in Madagascar in 1895, where the mortality from disease amounted to 300 per 1000 of strength. In this campaign there were killed by the enemy 7 and wounded 94, while the deaths from disease numbered 5600. The evils in the past were mainly due to lack of coördination and of real knowledge on which concerted action could be based. Nevertheless, advances were made, and as an example of the steady progressive improvement in the health conditions of the soldier, and the increased success in disease prevention, it is interesting to note that in India during the five years 1878–1882 the following were our sickness and mortality rates per 1000 of men serving among European troops. These figures may be compared with those for 1912:—

	1878–1882.	*1912.*
Constantly sick	68·1	28·8
Deaths	20·5	4·6
Malaria	559	82
Dysentery...	42·8	5·2
Cholera	5·7	0·3
	(4·2 deaths) ...	(0·2 deaths)

Certain excellent decisions which bore good results had been arrived at more or less empirically—for example, the spacing out of men in barracks recommended by the Herbert Commission of 1858, which in itself did so much to lower the incidence of tuberculosis and other diseases in the army.

Up to and including the Crimean War the medical service of the army had no fixed establishment of personnel. Indeed during that war some 240 enlisted men represented the total medical department in the field exclusive of medical officers. So impressed with the evils of this system were the committee who furnished the medical report of the Crimean War that they found it necessary to comment as follows:—

> "Without a trained hospital corps under the orders of the (medical) department superintending medical officers must be inoperative for all good; for without this aid they must see their best efforts lamentably fail to secure to the soldier all that is requisite to promote his comfort and bring about his recovery."

In addition, however, to the lack of personnel, conditions in the Crimea were largely due to lack of precise knowledge of the ætiology of the diseases which ravaged the troops. Two requirements were therefore necessary for the good of the army—namely, an organised personnel and increased knowledge. Up till the end of the century efforts were made to provide both with very fair success, so that at the time of the South African War the army was provided with an organised medical service having its own personnel, trained for its proper purposes and staffed by officers equipped with recent medical knowledge. The recommendations of the Herbert Report after the Crimea, indeed, went very much further, and the suggestions of that one illuminating document embraced all those improvements which were not fully provided until the lapse of over half a century. That report is noteworthy as suggesting an advisory board on hygiene as well as the early Army Medical School at Netley, and stands to-day as a lasting tribute to the foresight of its authors.

---

[1] Being an abstract of the first of three Chadwick lectures on Military Hygiene in Peace and War, delivered on March 8th, 1920.

CIRCULARS TO DOCTORS.

WE gather from the catalogue of the Agence de Publicité Denis Bodden in Brussels (82, Bd. Maurice Lemonnier) that there are 4045 doctors in Belgium, 2160 in Holland, 90 in Luxembourg, and 2334 in Switzerland. At all events, this firm is prepared to supply gummed addresses to these numbers for circulars, catalogues, and the like, at a cost of fr. 24, 15, 1 and 15 respectively.

DIPHTHERIA ANTITOXIN IN INFLUENZA.

WE have received from Dr. Robert Nairn, of Hastings, N.Z., a table of 41 cases (34 recoveries) of influenza treated with diphtheria antitoxin (4000 units). Temperature charts of many of the cases, of which 20 were complicated by pneumonia, show that a definite reaction, with rise of temperature, accompanied the antitoxin, followed by a fall about 48 hours after the injection. Dr. Nairn says that the subjective improvement was as marked as in cases of diphtheria. In a previous letter (THE LANCET, 1919, i., 635) Dr. Nairn suggested an ætiological resemblance between diphtheria and influenza. The beneficial effects of diphtheria antitoxin do not necessarily confirm this supposition, since normal horse serum has been found to possess markedly immunising properties.

CAUSES OF DEATH IN WEST AFRICA.

AMONG the vital statistics issued by the Colonial Office is an interesting record of the causes of death from disease among non-native officials in the group of West African colonies which includes Gambia, Sierra Leone, Gold Coast, and Nigeria. The causes of death during the year 1918 were: Blackwater fever, 6; heart disease, 2; dysentery, 1; carcinoma of stomach and liver, 1; gastric hæmorrhage and subphrenic abscess, 1; alcoholism, 1; influenza epidemic, 27—i.e., influenza, 13; influenza and pneumonia, 8; influenza and congestion of the lungs, 1; influenza and malaria, 1; pneumonia, 3; pneumonia and malaria, 1. The absence of deaths from malaria, except in conjunction with influenza, and from yellow fever, is an encouraging feature, and had it not been for the influenza epidemic the death-rate in 1918 would have been the lowest on record.

THE EFFECT OF AMERICAN RELIEF ON THE MORTALITY-CURVE OF CHILDREN IN VIENNA.

WE have received from Mr. Walter Lyman Brown, Director for Europe of the American Relief Administration, European Children's Fund, a chart showing the comparative mortality of children in Vienna, between the ages of 6 and 15, for the years 1917, 1918, and 1919. The chart, which does not readily lend itself to reproduction, has been studied by Professor von Pirquet, general Austrian commissioner of the Amerikanische Kinder-Hilfs-Aktion, and Dr. Mayerhofer, his chief assistant, who have made the following statement:—

> "So far as it is permissible to draw conclusions from statistical figures and the curves derived therefrom, we are justified in deducing from the material before us that the American feeding work has considerably influenced the death-rate of children. We see a drop of the death-rate from 158 in June, 1919, to 73 in November, a drop which is not evident to such an extent during the years of 1917 and 1918.
>
> The course of the curve showing the mortality which could have been expected without the feeding work is indicated by the blue line. We must emphasise in justice to the feeding work that at the end of 1919 the death-rate of the children between the ages of 6 and 15 years has been continuously the lowest since 1917. This is so much the more remarkable, as in the autumn and winter of 1919 a heavy epidemic of measles and a beginning influenza epidemic appeared."

We agree that a study of the chart bears out this deduction, which will be an encouragement to those who are engaged in this labour of love to redouble their efforts.

POLICE-AIDED SCHEME FOR CLOTHING DESTITUTE CHILDREN.

Sir William Gentle, who has just resigned the office of Chief Constable of Brighton, will be remembered as the originator, in February, 1904, of the Police-aided Scheme for Clothing Destitute Children. King Edward VII. once visited the police station at Brighton and saw the scheme in actual working. Little was done during the war period, but it may be hoped that Sir William Gentle, before finally relinquishing his office, will revive the work. During the winter months the police frequently observe children in the streets insufficiently clothed and consequently exposed to danger and suffering. The constable reports names and addresses to the superintendent of his division, who directs inquiries to be made. The homes of the children are then visited by the police, and if the fathers are found to be earning sufficient they have to provide adequate clothing for their children or are prosecuted under the Prevention of Cruelty to Children Act. If it be found that the parents are out of employment, and consequently unable to provide suitable clothing, garments are provided. There is no fear of the garments finding their way to the pawnshops, as each article bears a particular mark, and that mark is placed in the possession of the pawnbroker. Girls are also assisted so as to be able to enter domestic service. The war has changed the conditions in many ways, but there is no doubt that in Brighton, and in the other towns which copied the example, there is still scope for a continuance of this humanitarian work which changed the common conception of the policeman so that he came to be looked upon as a friend rather than as an enemy.

THE REDUCTION OF THE BREAD SUBSIDY.

WE live in an age of big figures, and the announcement of the Government of their intention to reduce the bread subsidy in the coming financial year by 45 millions gives some idea how the nation was helped to get its bread at relatively modest prices through the war. It is stated, in fact, that if no change were made the cost to the Exchequer on present estimates would be approximately 90 millions. The price of the loaf after April 12th will be in the neighbourhood of 1*s.* as against 9½*d.* at the present time. The average rate of extraction of flour required to be obtained from the ground wheat is also to be raised from 77 to 80 per cent. Experience has shown that the increased extraction of flour in the past did not lead to disturbance of health, and there is no suggestion to make a loaf of anything but wheat. At certain times through the war the extraction exceeded 90 per cent., and the admixture with other cereals and flour was authorised. Our bread is to remain a pure wheat product.

MINISTRY OF PENSIONS: REGIONAL COMMISSIONERS.

WE have published from time to time (THE LANCET, 1919, ii., 119 and 813) the names of the regional commissioners of the Ministry of Pensions and the boundaries of the areas over which they hold jurisdiction. To these commissioners has now been entrusted the responsibility of obtaining for disabled officers and nurses the medical or surgical treatment to which they are entitled. A discharged officer or nurse who is claiming retired pay or pension on the ground of disability attributable to or aggravated by service and who is in need of treatment should apply to the commissioner of medical services at the regional office. The revised list of the regions, with their respective commissioners and county boundaries (C.B.) is as follows:—

1. Scotland: Dr. G. H. R. Gibson, D.S.O., Adelphi Hotel, Cockburn-street, Edinburgh. C.B., all Scotland.
2. Northern: Dr. Hugh Richardson, D.S.O., 14, Clayton-street West, Newcastle-on-Tyne. C.B., Northumberland, Durham, Cumberland.
3. North-Western: Dr. A. H. Williams, 13, Piccadilly, Manchester. C.B., Lancashire, Cheshire, Westmorland, Isle of Man.
4. Yorkshire: Dr. C. H. Milburn, O.B.E., 7, Boar-lane, Leeds. C.B., Yorkshire.
5. Wales: Dr. Bickerton Edwards, O.B.E., Angel Building, Cardiff. C.B., All Wales and Monmouthshire.
6. West Midlands: Bethany Buildings, Loveday-street, Birmingham. C.B., Staffordshire, Shropshire, Warwickshire, Worcestershire, Herefordshire.
7. East Midlands: Colonel A. B. Ward, D.S.O., Black's Building, Stoney-street, Nottingham. C.B., Leicestershire, Lincolnshire, Nottinghamshire, Derbyshire, Northamptonshire, Rutlandshire.
8. South-Western: Dr. James Young, Clifton Down Buildings, Bristol. C.B., Gloucestershire, Wiltshire, Dorsetshire, Somersetshire, Devonshire, Cornwall.
9. Eastern: Dr. T. Basil Rhodes, 80, Westbourne-terrace, W. 2. C.B., Norfolk, Suffolk, Cambridgeshire, Huntingdonshire, Essex, Bedfordshire, Hertfordshire, Buckinghamshire, Oxfordshire, Berkshire.
10. London: Dr. H. J. Neilson, C.B.E., Crown Agents' Annexe, Westminster House, Millbank, S.W. 1. C.B., Metropolitan area.
11. South-Eastern: Dr. R. McLeod Veitch, 48, Grosvenor-gardens, S.W. 1. C.B., Kent, Surrey, Sussex, Hampshire, Isle of Wight, Channel Islands.
12. Ulster: Dr. A. E. Knight, D.S.O., M.C., Grand Central Hotel, Belfast. C.B., Ulster.
13. Ireland, South: Dr. D. A. Carruthers, Dunlop House, Abbey-street, Dublin. C.B., Munster, Leinster, Connaught.

Communications with regard to retired pay or pension should be addressed to the Officers' Awards Branch, Cromwell House Annexe, Millbank, London, S.W. 1.

THE MAGNET AUTO-STERILISER.

THE General Electric Co., Ltd., of 67, Queen Victoria-street, London, E.C., have recently introduced a steriliser for surgical instruments which should prove convenient in practice. It is described as being made on the "magnet" principle—i.e., with easily replaceable heating element (immersion type)—the apparatus including a heat-insulated handle for raising the lid besides a perforated self-draining tray, which is automatically lifted out of the liquid by lever hinges when the lid is raised. The liquid is rapidly brought to the boiling point and the heating elements can be supplied adjusted to varying voltage main supplies. The modus operandi is to fill the containing vessel with water, so that the immersion heater is well covered and the instrument tray properly immersed. The current is then switched on, and as soon as sterilisation is assured the lid is raised by means of the heat-insulated handle. The instrument tray is thus lifted out of the water, and the instruments dry rapidly by residual heat. Condensed water formed on the lid is caught in a trough receptacle and returned to the water-container when putting back the lid to its position. It seems to us that it would be an advantage to use distilled water in the steriliser, as then no film of mineral salts would be left on the instruments when automatically drying.

MEDICAL AFFAIRS IN BIHAR AND ORISSA, 1918.

THE population of Bihar and Orissa, including Chota Nagpur, at the census of 1911, was 34,489,846, and on this basis the ratios for births, deaths, &c., have been calculated. The birth-rate was 37·5 and the death-rate 56·7 per 1000, as compared with 40·4 and 31·5, the corresponding ratios for the preceding quinquennium; the decrease in the birth-rate was general in both urban and rural districts, only 4 of which out of the total 21 recorded a higher ratio than in the quinquennium.

This decrease is considered by Dr. S. N. Tiwari, the officiating Sanitary Commissioner, to have been due chiefly to the extensive and virulent epidemic of influenza, and partly also to defective registration and a general low vitality of the population from prevalence of fever and dearness of food during the previous two years. All the other provinces of India showed a similar reduction except Assam. The enormous increase in the death-rate from 35·2 to 56·7—that is, a total of 741,632 more deaths than in the previous year—was due chiefly to influenza; every province in India showed an increase from this cause, and many in a much greater degree.

In Bihar the two divisions of Patna and Chota Nagpur had fever death-rates of 50·3 and 48·7 per 1000, which were respectively 30·7 and 29·2 per 1000 in excess of the quinquennial average, this increase being due to influenza. In the district of Palamau (Chota Nagpur) the fever death-rate was 59·2; the highest fever death-rate for a town was 61·1 per 1000 at Balasore, of which 40·4 per 1000 was due to influenza. Remedial measures in all districts were undertaken by local bodies helped by the Government, but on account of the very rapid spread of the epidemic throughout the province no pathological investigations or preventive measures could be carried out beyond circulating leaflets giving general information about the disease and care of the patient.

In a concluding paragraph of his report Dr. Tiwari admits that "the existing sanitary organisation in the province failed to make any impression in preventing or combating the several epidemics which prevailed during the year," and points out that the responsibility of providing for and looking after sanitation rests with the local bodies who administer the law. The sanitary department, as at present constituted, is mainly an advisory body, and has no powers or funds at its disposal even to disinfect a well. Considerable progress, however, was made during the year 1919 in waterworks, sewerage, and general sanitary improvements, as detailed in the report by Mr. F. C. Temple, C.E., the sanitary engineer to Government.

Hospitals and Dispensaries.

From the report on hospitals and dispensaries in these provinces it appears that a total of 2,894,567 patients were treated in 1918, of whom 39,523 were in-patients. 60·92 per cent. of these latter were cured, 14·93 per cent. were relieved, 13·22 per cent. "discharged otherwise," 7·20 per cent. died, and 3·73 per cent. remained under treatment at the end of the year. The daily average number of in-patients was 1646·9.

It is stated that "cholera gave 22,731 admissions with 315 deaths, against 12,825 and 316 respectively in 1917." These figures give case-mortality ratios of 1·38 and 2·46 per cent. respectively. There must be some error here, as such low ratios seem to be incredible. In cholera epidemics the case-mortality varies considerably, from 30 to 50 per cent., but is never so low as here stated.

Note.—The details for 1918 are given in the tables accompanying the report. 699 cases were treated as in-patients (with 273 deaths) and 15,803 (deaths not stated) as out-patients at the State public, local fund, and private-aided dispensaries; 68 and 457 cases were similarly treated in the State special and railway dispensaries (with 30 deaths among in-patients); 5704 cases were treated (in- and out-patients) at private non-aided dispensaries. Of these 5704 cases 12 only are stated to have died. The returns are obviously incomplete.

Surgical operations.—The record of surgical operations is very satisfactory. The total number of all kinds performed in the State public, local fund, and private-aided dispensaries was 124,889, in 119,413 of which a cure was effected. Colonel G. J. H. Bell, C.I.E., I.M.S., Inspector-General of Hospitals and Dispensaries for the province, alluding to the "provincialisation" of the Patna General Hospital in April, 1918, states that he is in favour of this step being taken for the "sadr" (that is, principal) hospitals at all headquarters of districts on a similar basis to what is being done in the Madras Presidency. The expansion of these hospitals appears to involve more expense than can, in many instances, be met by municipal bodies.

Vaccination.—As regards vaccination in these provinces the total number of operations performed was 972,423, being a decrease of 125.253 compared with the previous year. This is ascribed to the prevalence of influenza, and was general throughout the whole region. 97·52 per cent. of the vaccinations were successful.

The mortality ratios for small-pox during the last five years have been 0·22, 0·42, 0·28, 0·19, and 0·17 per 1000 respectively. Dr. Tiwari considers that the decline in the death-rate is not likely to continue "except in the areas where the Vaccination Act has been made compulsory." This is now the case in all municipal towns; opposition has diminished, and is now shown not so much to vaccination itself as to vaccination of an infant under a year old. He recommends that vaccination be made compulsory throughout the province. With regard to inspection of results there appears to have been some difficulty; "villagers generally resent bringing their children for inspection; the system of thorough inspection of the work done in rural areas has suffered by the spirit of independence pervading villagers, resulting in numbers of children not being produced, even for short distances, for the civil surgeon's personal inspection."

Jail Population.

The year 1918 was remarkable for a very large increase in the jail population of these provinces. In 1917 there had been a daily average of 7182 prisoners, while in 1918 the average was 9199.

There was a great increase in sickness and mortality, much larger than would be warranted by the mere increase in numbers: the admissions to hospital were 13,777, compared with 6679; the average daily number sick was 662·3, compared with 310·1; and the deaths 584, compared with 237 in the previous year. In ratios per 1000 the hospital admissions were 1497, compared with 930; the daily average number sick 71·9, compared with 43·1; and the deaths 63·4, compared with 32·9. In the case of several jails the mortality ratios were excessively high—e.g., Daltonganj (226·2 per 1000), Purulia (199·6), Sambalpur (157·3). It is stated that several jails, especially Purulia, Arrah, Bhagalpur, Puri, and Chapra were badly overcrowded on account of rioting at Arrah at the festival of Bakr-id; also that a large number of prisoners on admission to jail were in a very bad state of health from epidemic influenza and its effects or tuberculosis. Taking the jails as a whole, of the 15,811 convicts discharged during the year from central and district jails, 54·67 per cent. had gained weight and only 19·72 per cent. had lost weight.

Lieutenant-Colonel B. J. Singh, C.I.E., I.M.S., Inspector-General of Prisons, who presents this report, considers it essential that a Juvenile Offenders Act should be passed (as in England), empowering magistrates to give two years' detention in a juvenile jail in lieu of a short term in a criminal jail. This would appear to be a sound recommendation. It is good to learn that the boys now play football.

Communications, Letters, &c., to the Editor have been received from—

A.—Mr. H. H. Armstrong, Olney; Prof. J. G. Adami, Liverpool.

B.—Bodleian Library, Oxford, Librarian of; Dr. E. C. Bevers, Oxford; Sir J. Barr, Liverpool; Dr. J. L. Brownlie, Glasgow; Mr. F. W. Brunker, Edinburgh; Mr. R. L. Bland, Lond.; Major S. T. Beggs; Mrs. C. Brereton, Lond.

A Presidential Address
ON
HUNTER, GASKELL, AND THE EVOLUTION OF THE NERVOUS SYSTEM.

Delivered before the Hunterian Society on Feb. 25th, 1920,

By W. LANGDON BROWN, M.A., M.D. Cantab.,
F.R.C.P. Lond.,

Gentlemen,—In his fascinating and inspiring centenary address Professor Arthur Keith laid stress on three salient features of Hunter's researches. Their importance was not fully recognised by those who came immediately after him; he was not concerned in the practical bearing of the investigations he undertook, and they ranged over the whole of the biological sciences, because each discovery in its turn raised so many new questions.

In the discussion that followed we agreed that all these characteristics were exemplified in Gaskell as in Hunter. Gaskell was one of the greatest minds of the nineteenth century, as Hunter was one of the greatest in the eighteenth. Yet, although he has been dead but a few years, I note a tendency in certain quarters to belittle the value of Gaskell's contributions to science. The reaction will come, as it came in Hunter's case, and justice will be done some day. Again, Gaskell was not in the least concerned with the practical bearing of his researches, but he was indefatigable in the search for truth, and as Starling says:—

> "In physiology, as in all other sciences, no discovery is useless, no curiosity misplaced or too ambitious, and we may be sure that every advance in the quest of pure knowledge will sooner or later play its part in the service of man."

This is abundantly true of Gaskell's work. Thus, in regard to his investigations on the heart, Sir James Mackenzie once said to me: "The further I go the more clearly I realise that Gaskell was the man." The clinical importance of his work on the sympathetic nervous system was, perhaps, appreciated in America sooner than in this country, but practical problems arising from the war have now forced them upon our notice. The ever-widening circles of interest which arise from investigation of a single problem is also clearly seen in Gaskell's work. He started by researching on the variation of blood-flow through a limb produced by muscular action. This led him to study the innervation of the blood-vessels and the nature of cardiac rhythm. This, in its turn, led him to investigate the plan of the sympathetic nervous system, which, he found, formed part of a larger system of involuntary nerves with visceral functions. Thereby he was able to determine a segmental arrangement of the whole vertebrate nervous system, which led him on to the morphological problem of the origin of the vertebrates. Many have regretted that he spent so much time and ability on a question which they regard as insoluble; yet it may be claimed, at any rate, that if he did not solve the problem he elicited a whole series of facts of great interest, and has compelled us to look at the evolution of the vertebrates from a new standpoint.

The Evolution of the Vertebrate Nervous System.

I may summarise Gaskell's view of the evolution of the vertebrates in the briefest possible manner, thus:—

In cœlenterates the central nervous system formed a ring surrounding the mouth. When symmetry became bilateral instead of radial and the animal became elongated and segmented, the œsophagus was still surrounded by a ring of nervous tissue. But this proved to have a serious drawback. The law of progress is this—The race is not to the swift, nor to the strong, but to the wise. Increased development of the central nervous system is the essential requisite to this progress; in the great reptilian age the denizens of the earth had far inferior brains to the lords of creation in later times. This is true also of the invertebrates. As we pass from the sponges to the arthropods progress is manifested, first by the concentration of nervous material to form a central nervous system, and then by the increasing bulk and complexity of that nervous system until its culmination is reached in scorpions and spiders. No upward development is possible with degeneration of the central nervous system, and in all those cases where a group owes its survival to degeneration the central nervous system shares in the degeneration. On the other hand, if an animal spends part of its life in a larval condition, and then is transformed into a higher adult form, as, for instance, when a caterpillar turns into a butterfly, or a tadpole into a frog, although there is an extensive destruction of the larval tissues, the central nervous system never shares in this; amidst the ruins of the larva it remains, leading and directing the process of reformation. In the arthropods the larval alimentary canal may be entirely destroyed and eaten up by phagocytes, while the central nervous system not only remains intact, but increases in size.

There is, therefore, ground for postulating the formation of a new alimentary tract, but none for the formation of a new central nervous system. Comparatively early in evolution a conflict is seen between the development of the central nervous system and of the alimentary tract. The highest arthropods developed the central nervous system until it gripped the œsophagus so tightly that they could only continue to exist as blood-sucking animals, such as spiders and scorpions. Thus when vertebrates first appeared the progress of the arthropods was leading to a terrible dilemma—either the capacity for taking in food without sufficient intelligence to capture it, or intelligence sufficient to capture food and no power to consume it. This mistake was rectified and further evolution secured in the vertebrate type by the formation of a new food channel, in consequence of which the brain was free to develop to its fullest extent, growing around the old alimentary canal, which became the central canal of the central nervous system. The infundibular tube represents the old arthropod œsophagus which leads into a large stomach situated in the head, represented in the vertebrate by the ventricles of the brain. The arthropod stomach leads into the straight narrow intestine, just as in the vertebrate the fourth ventricle leads into the straight narrow canal of the spinal cord. In the vertebrate embryo the canal of the spinal cord is joined to the anus by the neurenteric canal, which represents the terminal part of the arthropod intestine.

And here may I interpolate that if the central canal of the nervous system is thus a vestigial structure it might be expected to show, like other vestigial structures, a liability to disease. I would suggest that this might help to throw light on the obscure pathology of three diseases connected with the epithelium of the central canal—Friedreich's ataxia, disseminate sclerosis, and syringomyelia. I was therefore interested to read the report of a case[1] in which disseminate sclerosis and syringomyelia co-existed, again pointing to a common origin.

---

[1] M. Robertson: Review of Neurology and Psychiatry, vol. x., No. 10.

Geological Evidence.

Gaskell also adduced geological evidence in support of his theory.

> Each successive advance in the vertebrates started from the dominant type then existing—mammals from reptiles, reptiles from amphibia, amphibia from fishes. We might, therefore, expect that fishes arose in their turn from the race which was dominant when they first appeared. This was in the Silurian age, when sea-scorpions, king-crabs, and trilobites constituted the dominant race of Palæostraca. And the first fishes resembled Palæostraca so closely that it is often difficult to tell whether an individual fossil is an arthropod or a fish. It is very suggestive that the lowest non-degenerate vertebrate, the lamprey, resembles the king-crab in its larval stage, shedding its arthropod features when it is transformed to an adult.

In the evolution of the nervous system there is a parallel development of structure and function; reflex movements came first, and were possible with a simple form of nervous system such as is presented by the parts concerned in a spinal reflex; then as the supra-œsophageal ganglion became larger and more differentiated, more complex and automatic acts become possible. There is a general agreement among comparative anatomists, I believe, that the supra-œsophageal ganglion of the invertebrate is homologous with the corpus striatum of the vertebrates. The globus pallidus of the corpus striatum represents practically the whole forebrain in the fishes. This centre for automatic action enables the fish to keep up those coördinated rhythmical movements which are necessary to maintain its equilibrium in a fluid medium. With the assumption of terrestrial habits these constant movements would be a hindrance rather than a help. Hence the development of the brain cortex with its inhibitory mechanisms. This is one reason why the newer cortical system so constantly represses the activity of lower centres; it was originally evolved for that purpose. Hence its damage in early life results in a return of rhythmical movements in the form of athetosis. But it did not stop there; for while automatic movements are retained for primitive purposes the cortex not only keeps them in check, but moulds them into those higher forms of movement which we call voluntary. And as the pre-frontal region develops, it in its turn exercises control over both voluntary and automatic movements, restraining emotional expression but increasing skill through increased intelligence.

RECENT VIEWS ON THE EVOLUTION OF MAN.

In this connexion Elliott Smith's recent views on the evolution of man are of interest.

> He regards the Tarsius rather than the Lemur as nearest the direct line of human ancestry. Below the mammals the dominant sense is that of smell, but the Tarsius by shortening its nose was able to bring its eyes forward and achieved stereoscopic vision. The increased information thus afforded as to the shape of things developed skilled movements of the hands and a finer sense of touch, with a corresponding cortical area to correlate touch with vision. Man, he says, represents the straight line of development. It is the animals which have departed from this straight line and for self-preservation have developed specialised characters (e.g., the great strength of the gorilla), which have failed in the race for supremacy. Man has developed and become the greatest of the primates because of his faithful dependence upon development of the brain. The key to evolution lies in the continuous development of the nervous system.

Here, as elsewhere, the individual repeats the history of the race. Fœtal movements begin when the tracts connected with the corpus striatum acquire their medulla—i.e., when the fœtus is a fish swimming in amniotic fluid—while the pyramidal tract from the cortex does not become myelinated until the infant begins to walk. And the pyramidal tract announces itself as a new arrival in the spinal system by being the most variable in its position in different species; the last to appear has to accommodate itself to the space left for it by the others.[2] This difference in the history of these structures is correlated with a difference in the symptoms they present when diseased. Thus, while lesions of the basal ganglia, as in progressive lenticular degeneration and Parkinson's disease, cause tremor, rigidity, and weakness, defects in the pyramidal tracts lead to an extensor response, spasticity, and paralysis of voluntary movement. As on the motor, so on the sensory side. The optic thalamus represents an older receptive structure than the sensory cortex. Head and Gordon Holmes have shown that while the stimuli which appeal to the thalamus have to encounter a higher threshold before they can enter consciousness, they tend when effective to produce too marked and too prolonged a change. This the cortical mechanism has to control. The sensory cortex, on the other hand, has a quick reaction-time and a low threshold. It enables attention to be concentrated on any part of the body that is stimulated, and the sensations to be brought into relation with other sensory processes, past and present. It contributes, therefore, towards that control of feeling and instinct which is necessary to evolutionary progress. Or to take another example, man, having laboriously acquired the power of speech, has to learn the still more subtle art of silence.

THE INFLUENCE OF THE GREGARIOUS HABIT.

Just as the evolution of the individual is marked by greater powers of reaction and yet by a more controlled display of that power, so this process widens from the individual to the community of which he forms part. Self-control has to be learned, not only to divert energy into higher channels, but for the sake of others. Twice a "fault" in evolution has occurred: once when the dilemma between nutrition and intelligence was allowed to arise among the invertebrates, and again in the development of the huge mesozoic reptiles. The complete disappearance of these enormous animals recalls how frequently the worship of the ideal of the colossal, or shall I say "Kolossal," has heralded a downfall. It may be claimed that these gigantic reptiles were adapted to existing conditions, and vanished when those conditions changed. And yet there is something about them that inevitably suggests the 'prentice hand; just as there is about the first railway engine, the first motor-car, or the first "tank." Anyhow, mere bigness was then exploited to the full and found wanting. Now, it is important to note that on both these occasions a way of escape was found in gregariousness—the substitution of coördination between smaller individuals: firstly, for increased complexity of brain; and secondly, for mere increased size of body.

The enlargement of the unit exposed to natural selection by the development of a coördinated herd, in which each individual is absorbed into the community and is helpless apart from it, marks as distinct an advance in evolution as that from unicellular to multicellular organisms, and is fraught with even greater possibilities. For bees and ants this development was comparatively easy. A swarm of bees, says Trotter,[3] produces the illusion of a single animal, differing from the other metazoa, which it has outdistanced in the race of evolution, not merely in its immense power, energy, and flexibility, but also in the almost startling fact that it has recovered the gift of immortality which seemed to have been lost with its protozoal ancestors. Now it is to the very smallness of the brain of the individual bee, and the limited number of reactions of which it is capable, that the early attainment of complete success in the organisation of the hive is due. But, as he points out, for the mammals, with their greater powers of varied reaction, the path to the consummation of the possibilities offered by gregariousness must of necessity be longer, more painful, and more dangerous, and this applies in an altogether special degree to man. According to H. G. Wells, the change from the Palæolithic huntsman to the agricultural Neolithic man marks the stage at which self-suppression had to begin. "Man then entered upon the long, tortuous, and difficult path for the common good, with all its sacrifice of personal impulse, which he is still treading to-day." But I doubt if even Palæolithic man escaped from the control of the herd.

---

[2] Tilney: Journal of Mental and Nervous Diseases, vol. xlvi., p. 81.

The first law of the herd is, "Thou shalt not." Just as the development of the higher nerve centres leads to inhibition of instinctive activities, so the development of communal life must restrict the freedom of the individual. To take one instance —the history of mankind has been the story of a struggle for exogamy and monogamy in the interests of the race—and the very difference of our attitude towards a breach of these two laws is an indication of the length of the evolutionary phases which stretch out between them. It is curious that while the evolution of man's body from lower animals meets with general acceptance among educated people, the idea of a similar evolution of his mind is often found repellent. Yet it is clear that the individual recapitulates the history of the race mentally as he does physically, and with similar modifications. Just as the fœtus is a swimming fish profoundly modified by the protection derived by intra-uterine life, so the infant is a primæval savage, profoundly modified by helplessness and immaturity. Samuel Butler, who was too far ahead of his time for many of his evolutionary ideas to gain acceptance, expressed the same idea somewhat as follows:—

> Man begins as the primordial cell, splitting himself up, always doing as he did before but always with the additional experience gained by having done it once more. He will do his fish trick, so to speak, on his head, from long practice, and then the tadpole trick by rote. Then he grows arms and legs, all unconsciously, from the inveteracy of habit, but he has not learnt the lesson of human construction so thoroughly. Some parts of it, such as breathing, he is well up in, inasmuch as it forms part of previous rôles—but the teeth and hair, the upright position, the power of speech, though all tolerably familiar, give him trouble. Then comes his newer and more complex environment, and this puzzles him.

THE UNCONSCIOUS MIND.

Freud has done good service in emphasising the essential resemblance between the working of the childish and primitive minds. The myths of the ancients are repeated to-day in children's imaginations. It is not a mere accident that in fairy-tales it is the youngest son who slays the dragon and marries the princess, for just as fairy-tales express the attempts of the primitive mind to escape from the pressure of reality, so the child escapes from the feeling of inferiority in day-dreams. And elder children usually see to it that this feeling of inferiority shall be most experienced by the younger. When Dr. Montessori unreservedly condemns fairy-tales for children she forgets how natural, nay, how imperative, it is for the individual to repeat the history of the species mentally as he does physically.

And a reversion to this childish and primitive attitude of mind is seen in many forms of insanity. On the mental side, like Peter Pan, a psychoneurotic never grows up. As Hughlings Jackson said, there is a positive and a negative element in every case of insanity. In modern parlance the reality principle is in defect, the pleasure-pain principle is in excess.

But to a varying extent we are all still "puzzled by our environment." Man is possessed of powerful instincts, boundless desires, and a varying degree of reason. He has a considerable capacity for pleasure, and a much greater capacity for pain—his instincts drive him to seek the former and avoid the latter—his reason seeks after reality. Or if his reason does not seek it his environment forces it on his notice; most people tire of knocking their heads against stone walls, or of kicking against the pricks. As development proceeds the earlier mental phases tend to sink into the unconscious. Yet, as Bergson says:—

> "The past follows us at every instant, all that we have felt, thought or willed from our earliest infancy, is there, leaning over the present which is about to join it, pressing against the portals of consciousness that would fain leave it outside. The cerebral mechanism is arranged just so as to drive back into the unconscious almost the whole of this past, and to admit only that which can cast light on the present situation, or further the action now being prepared—in short only that which can give useful work. At the most only a few superfluous recollections may succeed in struggling through the half-open door. These memories, messengers from the unconscious, remind us of what we are dragging behind us unawares."

If I may change the metaphor, the surface current of the stream gives little idea of its force and depth; on which, however, its momentum depends. Samuel Butler[4] carried this idea still further back, expressing it beautifully in yet another metaphor.

> "His past selves are living in him at this moment with the accumulated life of centuries. 'Do this, this, this, which we too have done and found profit in it' cry the souls of his forefathers within him. Faint are the far ones, coming and going as the sound of bells wafted to a high mountain, loud and clear are the near ones, urgent as an alarm of fire."

And yet as we develop we remain more responsive to the far-off sounds than to the near ones. Indeed, as Otto Rank says,—

> "The detachment of the growing individual from the parental authority is one of the most necessary, but also one of the most painful, achievements of evolution."

To learn to see things as they are is the task of growing up. The unconscious mind employs only the pleasure-pain principle, which takes no account of time, as is well illustrated in dreams. The reality principle, recognising the element of time, does not demand immediate satisfaction, but can devote itself to the ultimate achievement of its aims. But since the pleasure-pain principle cannot be altogether abandoned it must be adapted and adjusted.[5] And out of defective adjustments psychic conflicts arise. I am as convinced that Freud is right in his general conception of the unconscious mind as I am that he is wrong in his limited view of the way in which it works. Its action is based on all the instincts, not merely on one. And we may adopt Dupré's epigrammatic classification of them—the instinct of self-preservation, relating to the life of the individual, the instinct of reproduction relating to the life of the species, the instinct of association relating to the life of society. In general the emotional conflicts which arise occur between the last and either of the other two.

---

[3] Trotter: Instincts of the Herd in Peace and War.

[4] Samuel Butler: Life and Habit, p. 52.

All who have studied the psychoneuroses of war are agreed as to the predominating influence of the instincts of the herd and of self-preservation. Or as Rivers[6] puts it:—

> "They depend upon a conflict between the instincts of self-preservation and certain social standards of thought and conduct, according to which fear and its expression are regarded as reprehensible."

And he points out in an interesting way the influence that the different training and responsibility of officers and men has in determining the type of neuroses they each develop. I have elsewhere compared some of these neuroses to the protective mimicry of insects, not a voluntary but an instinctive act. Rivers says:—

> "On the whole the officer is more widely educated than the private soldier: his mental life is more complex and varied, and he is, therefore, less likely to be content with the crude solution of the conflict between instinct and duty which is provided by such disabilities as dumbness or the helplessness of a limb. The histories of officers suffering from an anxiety neurosis often show the existence of temporary mutism, paralysis, or other functional disability in the early stages of their illness; but these solutions of their conflict do not satisfy them, and their disabilities speedily disappear to be replaced, sooner or later, by symptoms directly dependent on anxiety."

THE CONFLICT OF THE INDIVIDUAL WITH THE HERD INSTINCT.

A man may resolve his conflict with the herd instinct in one of four ways, according to Stoddart[7]:—

(1) "The herd instinct is voluntarily ignored, the delinquent avowing to himself that he has a perfect right to do as he likes." But few are prepared to become Ishmaels.

(2) "The conflict is condoned by 'rationalisation.'" This amounts to conscious or unconscious hypocrisy.

(3) "The emotional tone may gradually pass off as years roll by, and he becomes more occupied with other matters." Or, one might add, the emotion becomes sublimated into higher or more social activities—the best way of escape.

(4) "The memory is banished from consciousness, but not from the mind; an attempt is made to repress it so that it does not re-enter into consciousness. But repression may subsequently fail." Then it will prove the basis for neuroses.

PSYCHO-ANALYSIS *versus* SUGGESTION.

Now it is only the last solution which comes under our treatment. And it might be urged that, if psycho-analysis is right, suggestion is wrong as a therapeutic measure. Suggestion treats the symptoms by telling the sufferer there is no cause for their existence. Psycho-analysis professes to open the festering abscess, to drag the skeleton from the cupboard into the light of day. The bogey, stripped of its sheet and candle, becomes a turnip on a stick. And yet both have a common aim—to bring the sufferer into harmony with the herd. We are suggestible just because we are gregarious, but we are only susceptible to suggestions emanating from the herd. Psycho-therapy attempts to produce a more stable individual, adapted to his environment, but, as Trotter shows, not necessarily, and indeed not probably, a more adaptable being. It is not to the stable, adapted man that we look for progress. "A man is a fool or a physician at 40," runs the old adage. Perhaps both, you may say. Yet its meaning is clear. After 40 the normal man becomes less sensitive to his existing environment because he has fitted himself into it more or less, and philosophically recognises his limitations; but by that very fact he can the less adapt himself to a different one. Genius is permanently out of harmony with its environment, just as is insanity. Yet one could hardly regard with satisfaction the prospect of a world without the unstable elements that make for originality and brilliance. How much pleasure in life you and I would have missed had R. L. Stevenson been a healthy, normal individual. Have you ever read Leonard Guthrie's[8] history of the unemotional person? I quote only the latter part:—

> "He is a type of what is called a manly boy, without any nonsense about him; good-tempered, honourable, easy-going, not highly intellectual, but with a fair amount of common sense of a rather narrow order. He can obtain a pass degree at almost any university without much trouble. He makes an excellent clergyman of the muscular type, though perhaps a little intolerant of conscientious doubters of creeds which he never dreamed of questioning. In the army he is the idol of his men, who readily follow his leadership of a forlorn hope without blaming him for having made it so. In commerce he conducts a safe and never risky business, and, with capital and competent managers to guide him, will be prosperous. If wealthy he may develop a taste for art, and become renowned as possessing the finest collection in the country of pictures of the early Victorian British or 'Baby's birthday' school. In politics or religion he will stick to his party. Throughout his life he has no strong passions to battle with, care sits lightly upon him, and his ambitions are never thwarted, for he is perfectly satisfied with the state into which it has pleased God to call him."

In other words, he is admirably adapted to the herd, but he does not make for progress.

For the pressure of the herd, while developing altruism and perhaps raising the average level, tends on the other hand to discourage brilliant departures from that average. And it seems to me inevitable that the natural trend of evolution must be in the future, as in the past, in the direction of developing gregariousness, and that we must adapt ourselves to it or suffer for our departure from it. Therefore, I do not regard the curtailment of our personal liberty necessitated by the war as a temporary measure, but as a permanent change in the direction I have indicated. And we are beginning to realise from the misfortunes by which civilisation has been reduced to its present plight that the next step in gregariousness must be another enlargement of the unit, extending beyond the limits of any single race or nation.

---

[8] Leonard Guthrie: Functional Nervous Disorders in Childhood, p. 11

It is not likely, however, that the process which started at least as far back as neolithic times will be completed in the life-time of anyone here present. But such speculations lie outside my practical purpose, which is to call to your notice the part played by the sympathetic nervous system in certain neuroses and its close relationship with the unconscious mind.

The Origin of the Sympathetic Nervous System.

John Hunter applied the term "consciousness" to purposive though involuntary responses, while expressly stating that he was employing the word in a different sense from its usual one, preferring to do so rather than to coin a new word. To-day we use "consciousness" in a much more restricted sense, and certainly would not apply it to reactions occurring apart from the nervous system at all. Professor Keith said we now speak of such responses as chemiotaxis, and are no wiser. While this is substantially correct, it is an advantage to have a term which reminds us that the most primitive responses of animals are due to chemical stimuli, such as we see when a plasmodium creeps away from boiled water and towards an infusion of dead leaves. The development of a nervous system is a later event; it enables very rapid reactions to occur. Now, for what purpose would a rapid response be most vital? Obviously, for self-preservation.

These considerations explain certain fundamental facts. As differentiation proceeded the chemical stimulants or hormones became concentrated and specialised in certain ductless glands. The continuity of the species no longer depended on simple fission, but on the activity of special germ cells. The close association we note between the reproductive glands and the endocrine glands is thus based deep in evolution. Then, when the more rapidly reacting nervous system developed, while concerned with the functions of organic life, it would be most intensely active when a struggle for existence became necessary. The sympathetic nervous system is a mechanism adapted for rapid and widespread reaction in this struggle. Further, as this more rapid mechanism developed it might be expected to do so in connexion with the older chemical methods. So that as both endocrine glands and the sympathetic nervous system became specialised they remained associated. This association is reciprocal; not only does the sympathetic nervous system stimulate the secretion of certain ductless glands, but the secretion of some of them in turn increases the sympathetic response. Thus the sympathetic nervous system, the endocrine glands, and the gonads form a basic tripod entrusted with the duty both of the preservation of the individual and the continuity of the species. Their relationship is shown in disease as well as in health, and is reflected in many neuroses and psychoses.

Definite evidence in support of this association is provided by the researches of Dr. J. F. Gaskell, who has done so much to confirm his father's views. In the worms there are cells in the central nervous system which are the common ancestors of both the sympathetic ganglion and the adrenalin-secreting cell. Their development is parallel with that of contractile blood-vessels, comparable with vertebrate heart muscle, which are acted upon both chemically and nervously by these ancestral cells. They regulate but do not initiate the contractile rhythm—an interesting support to another Gaskellian theory. In the lowest vertebrate, the lamprey, there is a scarcity of sympathetic cells but a diffuse distribution of this adrenalin-secreting tissue, which controls the blood-vessels. In the course of evolution these cells have gradually given way to an increasing development of the sympathetic system, so that ultimately their only surviving remnant is the medulla of the adrenals. Thus, there is a gradual predominance of the nervous over the chemical element in the partnership as the higher levels of the nervous system are evolved.

Arrangement of the Autonomic Nervous System.

The starting point of Gaskell's observations on the sympathetic was his recognition of the small calibre of its fibres as they left the spinal cord. Adopting this as a standard, he showed that there were fibres with visceral functions in the cranial and sacral nerves. They may be called the parasympathetic, applying the name "autonomic nervous system" as an inclusive term for all these small fibres which carry out the functions of organic life without the control of the will. They form part of the primitive segmentation of the cord, but are absent from its cervical and lumbar enlargements, which are devoted to the innervation of those later developments, the great limb muscles. He showed that these small fibres represented the connector element of reflex action, and that their method of distribution outside the spinal cord enabled them to produce widespread effects.

Gaskell further showed that when the sympathetic and parasympathetic were distributed to the same structure they were antagonistic. Thus, the sympathetic dilates the pupil while the parasympathetic contracts it—the sympathetic accelerates the heart, the parasympathetic slows it. The sympathetic inhibits or diminishes the movements of the alimentary canal, while the parasympathetic increases them. Thus the reason for double innervation was explained, which Hunter had noted but could not understand. Speaking of the vagus in fishes, Hunter said—

> "Surely it must appear extraordinary that a nerve should arise from the brain to be lost in common parts, while there is a medulla spinalis giving nerves to the same parts. It must still remain one of the inexplicable circumstances of the nervous system."

Yet Hunter had got near to recognising why involuntary muscular actions should require a double nerve-supply without actually grasping it.

The Functions of the Autonomic Nervous System.

The rôles of the sympathetic and parasympathetic may be summarised thus. Sympathetic stimulation serves to activate the body for a struggle, and to increase its powers of defence. The pupil dilates to increase perception of light; the heart beats more quickly and more forcibly to supply the muscles with blood; the blood-vessels in the visceral area constrict, raising the blood pressure, and driving the blood from the digestive area, whose functions are simultaneously inhibited, into the skeletal and cardiac muscles, the lungs, and the brain. The sweat glands are stimulated to cool the body heated by its excessive muscular effort, and the hairs are erected in many animals to render them more alarming. As Crile[9] says:—

> "The mechanisms for self-defence which we now possess were developed in the course of vast periods of

[9] Crile: The Origin and Nature of the Emotions. Philadelphia and London. 1915.

time through innumerable intermediate stages from those possessed by the lowest forms of life. One would suppose, therefore, that we must now be in possession of mechanisms which still discharge energy on adequate stimulation, but which are not suited to our present needs."

The pilo-motor fibres are an example of this, for, however useful the erection of hairs may be to a cat confronted by a dog, the "goose-skin" experienced by man under emotional stress can serve no useful purpose. Some emotional responses, like some of our bodily structures, are vestigial remains.

Gaskell showed that the inhibitory action of the vagus on the heart is anabolic. The display of kinetic energy is replaced by the storage of potential energy. And Cannon[10] has extended this, pointing out that the functions of the cranial visceral fibres may all be regarded as anabolic. He says:—

> "A glance at these various functions of the cranial division reveals at once that they serve for bodily conservation: by narrowing the pupil they shield the retina from excessive light, by slowing the heart-rate they give the cardiac muscle longer periods for rest and invigoration, and by providing for the flow of saliva and gastric juice, and by supplying the muscular tone necessary for contraction of the alimentary canal they prove fundamentally essential to the processes of proper digestion and absorption, by which energy-yielding material is taken into the body and stored. To the cranial division of the visceral nerves, therefore, belongs the quiet service of building up reserves and fortifying the body against times of need and stress."

The sacral division of the parasympathetic consists of the pelvic visceral nerve. It may be regarded mainly as a mechanism for emptying.

> "Like the cranial division, the sacral is engaged in internal service to the body, in the performance of acts leading immediately to greater comfort." (Cannon.)

In pain, fear, rage, and any intense excitement the sympathetic neurons are brought rapidly into play, and the action of the cranial division of the parasympathetic is inhibited. In other words, the anabolic activities of the body are in abeyance, and the katabolic activities go on unchecked. Potential energy is converted into kinetic and reserves are freely spent. This is comprehensible now that we see these katabolic activities are defensive in origin and aided the primitive animal in its struggle with its antagonist, and that complex organism the State, when at war, like the individuals of which it is composed, inhibits its anabolic activities, spends its reserves, and brings into play every katabolic activity which can aid it in its struggle for victory. But exhaustion may follow.

The Action of Adrenalin.

The way in which adrenalin coöperates in all this has been admirably expressed by Cannon:—

> "Adrenalin plays an essential rôle in calling forth stored carbohydrate ...... flooding the blood with sugar; it helps in distributing the blood to the heart, lungs, central nervous system, and limbs, while taking it away from the inhibited organs of the abdomen; it quickly abolishes the effects of muscular fatigue, and it renders the blood more rapidly coagulable. These remarkable facts are, furthermore, associated with some of the most primitive experiences in the life of higher organisms, experiences common to all, both man and beast, the elementary experiences of pain, fear, and rage that come suddenly in critical emergencies. ...... The most significant feature of these bodily reactions ...... is that they are of the nature of reflexes; they are not willed movements; indeed, they are often distressingly beyond the control of will."

Now, one of the features of a reflex is its purposive character. If we seek for an explanation of the similarity of the sympathetic response to fear, pain, and rage, and other strong emotions, we may find it in Darwin's "Expression of the Emotions in Man and Animals":—

> "Great pain urges all animals, and has urged them during endless generations, to make the most various and diversified efforts to escape from the cause of suffering. ...... Whenever the emotion of fear is strongly felt, though it may not lead to any exertion, the same results tend to reappear, through the force of inheritance and association."

Crile illustrates this by a modern instance and a modern simile:—

> "And now, sitting at his desk in command of the complicated machinery of civilisation, when he fears a business catastrophe his fear is manifested in the terms of his ancestral battle in the struggle for existence. ...... Nature has the one means of response to fear, and whatever its cause, the phenomena are always the same, always physical." "Under modern conditions of life neither fight nor flight is de rigueur. The individual under the stimulation of fear may be likened to an automobile with the clutch thrown out, but whose engine is racing at full speed. The petrol is being consumed, the machinery is being worn, but the machine as a whole does not move, though the power of its engine may cause it to tremble."

The influence of this perturbation can be traced in many diseases. But we shall see these in truer perspective if we note the relationship of the autonomic to the rest of the nervous system.

THE INFLUENCE OF PSYCHIC CONFLICTS AT DIFFERENT LEVELS.

One of Hughlings Jackson's most illuminating generalisations was the conception of the evolution of the nervous system in three levels. Jelliffe has modified the original idea in labelling these the vegetative, the sensori-motor, and the psychic levels. However distinct in their evolution, the structures composing these levels have become inextricably intertwined. So that a disturbance originating in a viscus may produce a psychic disturbance, while conversely a psychic conflict may show its effect only at the vegetative level. If it shows its effect at the psychic level it may produce an obsession, if it sinks further into the unconscious it may produce a functional tremor, paralysis, or contracture; or sinking still further away may show its effect in the autonomic nervous system. If this effect tells mainly on the parasympathetic it may declare itself as asthma, arrythmia, slow pulse, hyperchlorhydria due to over-secretion, or enterospasm. If it tells on the sympathetic the results may be even more diverse. "The sympathetic system is at the mercy of the mind" said Leonard Guthrie. But in disease the action of the sympathetic, instead of being general, may become dissociated, throwing the machinery out of balance. Thus, over-stimulation of the sympathetic may mainly affect the vaso-constrictor nerves, producing a rise of tension, which is often seen to follow prolonged worry. Or it may cause atony of the stomach and bowels, with spasm of the associated sphincters, resulting in reflex dyspepsia and intestinal stasis. I need only mention in passing the production of gall-bladder and appendix dyspepsias in this way. Tyrrell Gray has recently emphasised the influence of visceroptosis in producing stasis not so much by leading to mechanical kinking, but by dragging on the sympathetic nerves in the mesentery and thus inhibiting peristalsis. Similarly, stasis may be initiated through the influence of mental shock, anxiety, or grief on the sympathetic. Thus we can understand why, though visceroptosis has been present since birth, it caused no symptoms until sympathetic inhibition supervened. We can also understand not only why a Curtis support may relieve symptoms of visceroptosis by raising intra-abdominal pressure, even though X rays show that it does not replace the viscera, but also why a happy marriage may be even more effectual. Not all our woes and ills depend on our having the presumption to walk on two legs instead of four.

---

[10] Cannon: Bodily Changes in Pain, Hunger, Fear, and Rage. London. 1915.

The influence of the sympathetic on the thyroid gland is profound. Cannon joined the central end of the phrenic nerve to the peripheral of the cervical sympathetic in a cat, so that the gland was stimulated with every breath. This resulted in tachycardia, increased excitability, diarrhœa, exophthalmos on the side of the operation, and a great increase in metabolism. In some cases there was an increase in the size of the adrenals. The whole aspect of the sufferer from Graves's disease resembles that of fear, and is produced through a similar nervous mechanism. Crile says:—

> "I have never known a case of Graves' disease to be caused by success or happiness alone, or by hard physical labour unattended by psychic strain, or to be the result of energy voluntarily discharged."

In this connexion note the epidemics of hyperthyroidism which followed the air-raids on London, the Kishineff massacres, and the San Francisco earthquake.

GLYCOSURIA.

Take, again, the case of glycosuria. When stocks go down in New York, says Crile, diabetes goes up. Temporary glycosuria occurred in a number of men who merely watched a football cup-tie without participating in it. I have been struck with the number of cases I have seen in young naval officers. I am inclined to refer its higher incidence in the senior service to the much greater responsibility which falls to the lot of junior officers. Diabetes is characterised, like sympathetic stimulation, by an exaggerated metabolism. This first shows its effect on the most abundant and most easily metabolised of the foodstuffs, the carbohydrates, which are also essential for muscular action, to which sympathetic stimulation should normally be a preliminary. It is noteworthy that the glands which increase katabolism and lower cabohydrate tolerance, the pituitary, thyroid, and adrenals, are all stimulated by the sympathetic. On the other hand, the pancreas, which is anabolic and increases carbohydrate tolerance, is probably inhibited by the sympathetic. Thus, we can understand why sympathetic stimulation through various disagreeable emotions should increase metabolism generally, and specially lower carbohydrate tolerance. And alimentary rest would diminish glycosuria by enforcing a more economical method of metabolism. Allen, who is one of the most convinced adherents of the pancreatic origin of diabetes, admits that a man may actually die of diabetes and yet have as good a pancreas as normal—so that a functional incapacity of the pancreatic cell-islets, due to some nervous influence, may be responsible. In his latest writings he lays considerable stress on the hydropic degeneration of these islets, while acknowledging this to be a result, and not a cause, of the disease. Even he admits, therefore, that ordinary diabetes shows itself through the pancreas rather than merely as a symptom of pancreatic disease. And I think I have shown that the views of Allen on the one hand and those of Eppinger, Falta, and Rudinger on the other concerning a loss of endocrine balance as the cause of diabetes find their reconciliation in its production through the sympathetic nervous system.

In this connexion I may quote two interesting cases recorded by Singer and Clark,[11] in which there was a definite alternation between the exhibition of mental symptoms and the presence of glycosuria, just as in catatonia the somatic disorders clear up during the mental disturbance, reappearing as the mental condition becomes clearer. It would appear as if the emotional discharge asserted itself either at the metabolic or the psychic level in such conditions and not at both.

I do not mean to imply that all cases of diabetes are necessarily dependent on a functional disturbance of the sympathetic nervous system. We are too ignorant of the morbid anatomy of the sympathetic to say this. In some diseases of the sympathetic, such as pellagra, definite structural alterations have been found, and there is a crying need for its systematic microscopical examination in diabetes. All I do claim is that diabetes can be most easily explained by a disturbance of the sympathetic nervous system, and that this disturbance can be produced by emotional stresses and strains. The frequency with which it occurs in that most emotional race, the Jews, and its association with families of a neuropathic tendency point in the same direction.

The fact that the cause of a vegetative neurosis is not always remembered is beside the mark. The patient would naturally tend to push it "out of his mind," which only means pushing it into that deeper level of the stream where, nevertheless, it is borne along. Nerve impulses tend to run along accustomed channels, whether those channels are conscious or unconscious. Indeed, the longer they are in use the more unconscious they become—a fact that is well illustrated in acts which primarily affect consciousness acutely, such as playing the piano or riding a bicycle.

THE DYNAMIC CONCEPTION OF DISEASE.

Disease means an attempt by the body to establish a new position of equilibrium, whether it is invaded from without or faced by a difficult environment. In this reaction every tissue and organ plays its part, but especially that master tissue the nervous system, through which our predominant position in evolution has been achieved. The dilated pupils, the sweating, the tachycardia and increased katabolism, together with the ultimate adrenal exhaustion produced by many infective fevers shows the similarity of its response to the seen and the unseen foe. In the view here presented there is no break between the chemical reactions carried out by the endocrine glands and the highest reactions of the most recently evolved nervous structures. Endocrinology and psychotherapy are not opposed but complementary measures, applicable to different ends of one system, and both ends may be involved in the same process. The difficulty in harmonising oneself with the environment may be due, in part, to failure in the chemical mechanisms. Psychotherapists are too apt to forget this, and may even suggest to an eminently suggestible subject an explanation of his complexes which springs from their own obsessions. I say this with fear and trembling, expecting the retort that such a remark is merely an interesting demonstration of my own complexes or resistances. But not even the youngest of our therapeutic or diagnostic measures is infallible. Yet it is just as erroneous merely to treat the patient as a test-tube in which certain drug reactions can be made to occur, and the man who does so not only fails to realise his responsibility but misses a most interesting part of his work. The old injunction to examine the whole of a patient must be interpreted to include the consideration of his environment in its widest sense. With this widened conception opening out before us, the practice of medicine becomes an occupation of even more absorbing interest, to which we can devote our lives with pleasure and enthusiasm.

HEAT HYPERPYREXIA.[1]

BY W. H. WILLCOX, C.B., C.M.G., M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON; CONSULTING PHYSICIAN, MESOPOTAMIAN EXPEDITIONARY FORCE, 1916–1919.

DURING the summers of 1916, 1917, and 1918 a large number of cases of illness due to exposure to high atmospheric temperature occurred amongst the troops in Mesopotamia, and it is upon a careful study of these cases that this paper is based.

Ætiological Factors.

First among these is *climate.* High temperature, coupled with the flatness of the country and absence of shade and the great humidity in certain parts owing to floods and swamps, make Mesopotamia one of the most dangerous countries in the world as regards risk of heat hyperpyrexia.

A maximum shade *temperature* of 110° F. appears to be the dangerous limit. When this is reached some cases of "effects of heat" are sure to occur, and each degree of rise above this limit is attended by an increasingly larger number of cases. Temperatures of 120° or over are exceedingly dangerous, and on these days, in spite of all precautions, large numbers of heat-stroke cases occur. A comparison of the temperature records of 1917 and 1918 for Baghdad shows the reason of the far greater number of cases of heat-stroke in the former year. Thus, in 1917, on six days in July the shade temperature was 120° and upwards, and on 15 days it was 115° and over. In 1918 the temperature did not reach 118°, and on only two occasions was it 115° or over.

The effect of heat is undoubtedly *cumulative* in action, one or two very hot days not necessarily being followed by a large number of cases of heat-stroke; it is the succession of several hot days which is dangerous. The case incidence curve follows the temperature curve with a delay of a few days in the rise of the former. The cumulative effect of heat is shown on the individual; thus a man may be exposed to heat for one or more days and then develop an attack of heat hyperpyrexia in the night or early morning after the atmospheric temperature has fallen considerably.

As showing the effect of *stagnation of air*, free currents of air have great protective value by promoting evaporation from the skin and loss of heat. Electric fans and punkahs were largely used in Mesopotamia in hospitals and dwellings occupied by troops from 1916 onwards. They were of vital necessity to the British troops during the hot months. When the temperature is very high the air from a fan is like a hot blast, and unless the body be covered with a moist sheet, or a moist screen intervenes, the fan is of little value as a cooling agency, and, indeed, may do more harm than good.

The risk of heat hyperpyrexia depends largely on personal protection, and if care be not taken any *age* is subject to it. The case-mortality is undoubtedly greater in men over 40.

The influence of *race* is very important. Heat hyperpyrexia, due to heat alone and not to the complication of other diseases, is very uncommon amongst Arabs and Indians; indeed, when it occurred in them some complicating disease, such as malaria, was almost always found as the cause. White races are much more susceptible to the effects of heat, and in British troops a large percentage of the cases was due to heat per se.

Exertion taken during the heat of the day is a great predisposing cause, especially if heavy kit is carried.

In regard to *predisposing diseases*, any disease causing pyrexia predisposes to heat-stroke in the hot weather. Malaria is one of the commonest of these, and in Indians was almost always the cause of heat hyperpyrexia. During an attack of sand-fly fever in the hot months hyperpyrexia occasionally occurred. Captain H. C. Sinderson has suggested[2] that sand-fly fever is a common cause of heat hyperpyrexia. I cannot agree with this, because in the great majority of cases of heat-stroke there is no evidence whatever of sand-fly fever, and during the great incidence in July and August, 1917, sand-fly fever was entirely absent. Enteric group disease, if occurring in the hot weather, is sometimes complicated by heat hyperpyrexia, as also is typhus fever both in the acute stage and apyrexial period. I have seen heat-stroke occur during the early stages of small-pox before the appearance of the rash.

Pathology and Morbid Anatomy.

I have no doubt that heat hyperpyrexia is a clinical entity and that it occurs apart from intercurrent diseases. The clinical history of cases of pure heat hyperpyrexia and the course of the symptoms after the acute stage, which often exhibit a prolonged pyrexia and profound toxæmia with the absence of any bacteriological infection, strongly indicate that the cause is an auto-intoxication as the result of the effect of heat on the body tissues. My experience leads me to believe that this is the cause of heat hyperpyrexia. The auto-intoxication occurring in heat-stroke cases was found to be associated with the presence of acetone and diacetic acid in the urine in only a small proportion of cases (about 12 per cent.), and in these the reaction was of only moderate intensity. It thus appears that heat hyperpyrexia is not due to an acid intoxication. The presence of indican in excess in the urine in acute cases is of importance and is an evidence of the auto-intoxication present.

Suppression of sweating did not, in my experience, always precede heat hyperpyrexia, and though it is undoubtedly an important predisposing cause it cannot be regarded as the primary one. Thus some cases of heat hyperpyrexia occurred suddenly in exposed men who were in good health without any previous evidence of lack of skin action, and in cases of the gastric type of heat hyperpyrexia no previous suppression of sweating was observed, though they had been under observation in hospital for several days.

---

[1] Abstract of paper read before the Medical Society of London on March 8th, 1920.

[2] Brit. Med. Jour., July 19th, 1919.

Clinical Types of Illness Caused by Exposure to Heat.

(1) Heat exhaustion (mild type); (2) gastric type; (3) choleraic or gastro-intestinal type; (4) heat hyperpyrexia (sunstroke). In types 1, 2, and 3 heat hyperpyrexia may suddenly develop unless great care be taken in the removal of patients from a hot atmosphere. Types 2, 3, and 4 are all dangerous, and in them the prognosis is grave. Of 80 severe cases of effects of heat, of which I made careful notes, 13 (16·2 per cent.) were of the gastric type, 9 (11·2 per cent.) of the choleraic, and 58 (72·5 per cent.) were hyperpyrexial.

Gastric type.—This is one of the most interesting and treacherous forms. The patient may have a flushed face, and be restless and irritable with marked nausea and occasional vomiting, the mouth temperature and pulse normal for several days, but the rectal temperature often rising about 2°. The liver usually shows a fatty enlargement. The knee-jerks were lost in all of nine cases on which it was specially tested. This is a valuable diagnostic sign. The knee-jerk reappears when convalescence is established, the time varying with the severity of the case. Many of these cases, after four to ten days of premonitory symptoms suddenly developed a fatal heat hyperpyrexia.

Gastro-intestinal type.—In this type the onset is sudden, marked collapse occurring. The patient usually has a temperature of 101° to 103° F. Vomiting is marked and diarrhœa occurs. There were cramps in the abdomen and legs in some of my cases. The face is pale, the eyes sunken, and the skin pale and clammy. The knee-jerks are generally lost; in 4 cases specially examined they were absent in 3 and diminished in 1. The general appearance of the patient is similar to that of cholera. This type was of uncommon occurrence, but the mortality was high, death often supervening within three or four days.

Heat hyperpyrexia.—The onset is often quite sudden, the patient being taken ill when on duty with a sudden high rise of temperature and loss of consciousness. In some cases the patient, when off duty, may be found by his comrades unconscious and dying. Heat hyperpyrexia frequently occurred in the very hot weather in hospital patients suffering from another disease. In them the temperature would often suddenly rise to 110°, coma and convulsions supervening.

In many cases, however, the onset is more gradual, malaise, headache, and restlessness occurring and sometimes nausea and vomiting. Frequency of micturition is a characteristic early symptom, and is sometimes associated with urethral pain. The temperature is somewhat raised, 100° to 102° or so, and the skin is hot and dry. These preliminary symptoms usually last for a few hours, sometimes as long as 48, after which mental excitement and delirium supervene and the temperature rapidly rises to about 110°. With the hyperpyrexia coma and stertorous breathing occur, the face is flushed and cyanosed, and the conjunctivæ congested. The pupils are often dilated in the early stage and contracted in the comatose condition. Fibrillary twitchings of muscles and convulsions are very common, and the breathing may be Cheyne-Stokes in character. Incontinence of urine and fæces accompanies the coma. Unless the temperature is reduced by treatment death rapidly occurs from hyperpyrexia, the mode of death usually being asphyxial in type.

Marked cardiac dilatation, often associated with a systolic murmur, occurs in the severe cases. This may remain for a few weeks after the attack and needs special care. In some cases bronchitis and congestion of the bases of the lungs occur. In one case definite air-hunger was observed, and in another a spasmodic type of breathing like that of uræmic asthma. Pulmonary œdema was a terminal event in the fatal cases.

On examining the urine, indican was found present in excess in all of 6 acute cases in which a special examination was made. Acetone and diacetic acid were found present in small amount in 1 out of 8 acute cases specially tested. Albumin was detected in small amount in 3 out of 8 acute cases. No casts were seen.

Of nervous symptoms, restlessness and delirium occur with the onset of hyperpyrexia, and are quickly followed by stupor and coma, with incontinence of urine and fæces. Muscular twitching and convulsions are very common with the high temperature. The knee-jerk is almost always absent in the pure heat-stroke cases during the acute stage. Out of 32 cases specially tested the knee-jerk was absent in 27, diminished in 2, and normal in 3; in these latter cases the hyperpyrexia was probably malarial in nature. In severe cases the knee-jerk does not return for three or four weeks, in milder cases it returns earlier. The presence of knee-jerks is a valuable prognostic sign, for when they have returned there appears to be much less risk of a relapse, and the patient may then be evacuated with safety. This sign was of great practical help in deciding on the disposal of heat-stroke patients. After the acute stage in the severe cases marked mental symptoms often remain for some weeks or longer; irritability, mental confusion, and delusions are not uncommon. Usually, but not always, these symptoms clear up. Defective articulation (anarthria) occurred as an after-symptom in 4 of the severe cases of my series. Nystagmus occurred in 1 case, and squint with diplopia in 1. Multiple neuritis associated with weakness and marked wasting of the legs, the tibialis anticus muscles being most affected, occurred in 2 cases.

Many of the severe cases after the hyperpyrexia has subsided show a pyrexia, the temperature remaining for several days about 102° or 103°. In 1 case the fever lasted three weeks. Numerous blood cultures were made on these pyrexial cases with negative result. Recurrences of hyperpyrexia are very likely to occur after a heat-stroke attack unless the patient is kept in a cool atmosphere, but this is often impossible.

Treatment.

For the gastric type of case removal to a cool atmosphere, bicarbonate of soda in frequent full doses by the mouth, and free purgation give the best results.

The choleraic type of case is treated on similar lines to cholera.

Heat hyperpyrexia demands treatment with sprays of ice-cold water and fans, quinine bihydrochloride being given intravenously or intramuscularly if there is the slightest suspicion of malaria. Convulsions are treated by venesection, or morphia or chloroform inhalations.

[The prophylactic measures were fully dealt with by the author.]

SYPHILIS AT A VENEREAL CLINIC:

AN ANALYSIS OF CASES ADMITTED DURING TWELVE MONTHS.

BY E. F. SKINNER, M.A., M.B.CAMB., M.R.C.P. LOND.,
ROYAL HOSPITAL, SHEFFIELD.

THE following notes are set forth merely as an analysis of cases that have been admitted to the clinic during the period August 31st, 1918, to August 31st, 1919. During this period of twelve months the methods of the clinic and the routine work have been uniform, and though the number of cases is small, some interesting features have developed, and may be of use in comparison with similar details from other clinics. 354 new cases of syphilis have been admitted during the 12 months, 229 males and 125 females; the ages of these patients have been analysed, and the admissions at various age-periods tabulated as follows:—

Age-period.	M.	F.	Age-period.	M.	F.
Under 1 year ...	3	7	Between—		
Between—			40 yrs. and 45 yrs.	17	7
1 yr. and 10 yrs....	5	5	45 ,, ,, 50 ,, ...	14	6
10 yrs ,, 20 ,, ...	16	23	50 ,, ,, 60 ,, ...	5	3
20 ,, ,, 25 ,, ...	54	28	At 66 yrs, ...	1	1
25 ,, ,, 30 ,, ...	56	21	Not stated.... ...	3	3
30 ,, ,, 35 ,, ...	32	16	—	229	125
35 ,, ,, 40 ,, ...	23	5			

It must be observed that these figures are not ages of incidence of disease, but ages at which patients have sought admission to hospital, and it is noticeable that nearly twice (1·8) as many males are admitted as females, whilst a glance at the table will show that during the early years (1–10) and the later years the sex incidence of admission is practically the same; thus the real difference in the male and female admission-rate occurs between the ages of 20 and 50, and during this period more than twice as many males as females are seen.

There are doubtless many reasons for this, but it seems likely that the knowledge of the existence of clinics and the dangers of venereal disease as set out in propaganda literature and public notices generally is not reaching the female population to the same extent as the male; consequently steps should be taken at once to approach women more directly, either through existing organisations or by other special means.

This inference drawn from the table of age admissions of the two sexes is borne out by experience in the clinic, for whereas many men state that they have come up because they have seen the various public notices it is only very rarely that women say this; further, whereas many men seek advice before any sign of disease has appeared or has had time to appear, women do not come up until symptoms have developed, and these usually in the secondary stage. This point will be referred to again under the examination of the Wassermann-reaction results. One important conclusion apparently can be drawn from the 12 months' work: namely, that the female population is not yet aware of the dangers of syphilis and of the existence and facilities of venereal clinics to anything like the same extent as the males, and that active measures to remedy this are urgently needed.

Absentees.

In every out-patient department of a general hospital there are always a certain number of patients who come once or twice and then disappear, and a venereal department suffers in this respect perhaps more than others, for two reasons: firstly, the venereal patient is apt to be a casual person, and not one given to much thought; and, secondly, because the régime is not such a comfortable one as that of an ordinary medical out-patient department. Considering these two points, it is surprising how relatively few patients do become absentees.

Out of 354 patients admitted with syphilis during the 12 months only 58, or about 16 per cent., have failed to complete the full course, and of these only 24 failed to complete the first three injections. These figures seem fairly satisfactory, but it would be interesting to know the experience of other clinics where a full routine is employed. The sexes are represented in these figures, thus:—

	M.	F.
Failed to complete first three injections ...	16	 8
Failed to complete full course	25	 7

If a patient fails to report at the clinic at his proper date his number is noted on a black list, and at the end of two months, if the absence still continues, a printed letter is sent to him informing him that his non-attendance has been noted, and that he is advised to come again for further advice. Such a letter, in a large number of the absentee cases, either brings the patient up again or produces a letter explaining the absence, which in the case of the men is generally that they have left the district in search of employment. This is a point of some importance, and as a practical inference it might be urged that in the notices issued by the L.G.B. as to clinics great stress should be laid on the necessity of continuity of treatment. If patients are compelled to leave a district the transfer form should be completed, and advice asked as to where they are to report themselves in the new district. These transfer forms are not sufficiently used.

I have laid stress on this, as it has seemed at times that discontinuity of treatment is worse than no treatment—that is to say, that symptoms of recrudescence after an incomplete course of salvarsan are occasionally more intense than the same symptoms would have been at the same period in an untreated case; this, however, is merely a clinical impression and cannot be supported by observed data.

Marital and Congenital Cases.

The next point of interest was the number of marital cases, and in this series of 354 the number was 42, or nearly 12 per cent. Of these, 14 wives infected their husbands and 28 husbands infected their wives—that is, twice as many males were unfaithful as females. This is not the place to discuss ethical questions, but though this figure is admittedly large, if the abnormal mental and physical strain of the past three years is taken into account it is not large enough to warrant some of the gloomy statements that have been made lately on the platform and in the press.

During the 12 months, 29 cases, or about 8 per cent., of congenital syphilis have been admitted and treated, 10 males and 19 females, and these may be divided into two groups, the infantile congenital syphilis and the "lues tarda." The first group includes the snuffles, dermatoses, anæmias, &c., while the latter group comprises keratitis, otitis, &c., and these two groups are represented as follows: Infantile group, 14 admissions; "lues tarda," 15 admissions.

Most of the first group came up from the maternity and child-welfare centre, whilst the second class of case generally comes from the special departments of the hospital. These cases have all been treated by means of intravenous or intramuscular injections of neo-salvarsan, and the results in the babies have been very satisfactory; the keratitis cases have not shown the same improvement, though here I have seen sufficient benefit, particularly in the younger cases, to warrant a much more sanguine prognosis than is usually given. The cases of otitis have not reacted so well and, from those I have personally treated, my conclusion would be that once the eighth nerve becomes involved the deafness is steadily progressive, a fact possibly due to the enclosed course of this nerve.

It would be of great benefit if at every maternity and child welfare centre there were facilities for doubtfully syphilitic babies, possibly the subjects of syphilis, to be seen at the centre by a venereal medical officer, who could at once transfer them to the clinic if treatment were considered necessary. Dr. H. Scurfield, the medical officer of health of Sheffield, has kindly granted me facilities for seeing any such doubtful cases, and I have found this privilege extremely valuable, as congenital syphilis is not always an easy thing to diagnose. To miss cases at present is almost a national disaster, not only on account of the individual child, but from the fact that the mother is very often unaware of any taint in herself. It may be mentioned here that pregnant women are carefully watched, and the full course of salvarsan given up to the middle of the seventh month (one case has been carried on up to the beginning of the ninth) without any ill results to the mother, and as early as possible after the baby is born the mother brings it up for inspection. Two fine babies have been born during the 12 months of mothers who have had complete courses, and though the time since their birth is very short (one is 10 months old) they are still both apparently healthy infants.

Incidence of Clinical Types.

Primary cases.—For the purposes of this analysis a case has been called primary when the presence of a sore is noted without any other signs of the disease except inguinal adenitis, and the number of cases falling into this category during the 12 months is 47, or 13 per cent., and of these only 5 were females. Primary cases (47): males, 42; females, 5.

A striking fact about these cases is that of the 42 men 31, or roughly 74 per cent., gave a negative Wassermann reaction when first seen, whilst of the women not one had a negative blood; in other words, the women present themselves later than the men, even though a few do come up during the early stage of the disease. This emphasises the conclusion drawn from the age-table previously given.

	Males.	Females.
Primary cases with negative Wassermann ...	31	0
,, ,, ,, positive ,, ...	11	5

Secondary Cases.

Unfortunately, this type of case still furnishes the largest number of admissions, and there is obviously a great deal of work necessary before the general public is sufficiently alive to the advantages of early treatment and the dangers of quack methods. A large number of men who come up during the secondary stage confess to having sought advice from such unauthorised sources, and many more attempt to carry out home treatment of their own devising. The number of secondary cases has been 238, or 64 per cent. of the total admissions, made up as follows: males 147, females 91.

Tertiary cases.—Forty cases of tertiary syphilis have been admitted, 30 males and 10 females. This figure is purposely kept small, as it seems clear that venereal clinics are not primarily intended for such cases, but a certain number have been put on the register for the sake of watching the effect of salvarsan on such conditions as aortitis and locomotor ataxia. Other cases of tertiary syphilis are given anti-syphilitic treatment, but are not put on the venereal department register as it seems unfair to saddle the department with the added financial burden of this type of case.

Wassermann Reaction.

During the routine course of treatment the blood is examined on three occasions, before the first injection, after the fourth, and also after the seventh, and on the results of these examinations, together with clinical evidence, the further conduct of the case depends. Each case must be judged on its own merits, and no hard-and-fast rules can be laid down, nor do I wish here to go into the details of how such decisions are arrived at, as this paper is intended merely as a summary of the work done at the clinic, and only one or two conclusions based on the year's work are mentioned. The facts elicited do not present any new features, but their recital may be useful.

Primary cases.—Of the primary cases, 47 in all, 31, all men, were admitted with negative W.R., and in none of these has the reaction subsequently become positive. Sixteen of these have completed their course; the remaining 15 are still under treatment. Of the 16 completed cases, 5 have had one Wassermann test after two months' observation, during which time treatment is limited to daily inunction with mercury, and two cases have passed their second period of observation (5 and 9 months respectively after admission), all with completely negative Wassermann reactions.

Of the 16 primary cases admitted with positive reactions, 13 have completed the course, and of these the Wassermann was negative in 11 on the second test (by which time—45 days after admission—1·3 g. of salvarsan have been given with 4 gr. of mercury) and has remained negative. Of the other 2 cases, one became negative after the fifth injection, and the other gave a doubtful negative after the last injection of the routine course. This last case is interesting, as there was an intermission of three months after the third injection. This behaviour of the Wassermann reaction leads to the view that only in the earliest stage, with a negative W.R.—that is, before it has become positive—can treatment be depended on to keep the W.R. permanently negative; once the W.R. has become positive, though it may be reduced to negative by active treatment, sooner or later it again becomes positive with or without symptoms. This is well seen in the secondary cases, who, of course, all give a strongly positive W.R. at the commencement of treatment.

Secondary cases.—Fifty-five have been picked out of the total number of secondary cases as these have all completed at least a full course and have had all the necessary tests recorded. Of these, all starting with strongly positive (+ + +) bloods, 34 have given negative W.R. (−) at the end of the course, 4 have given a doubtful negative (±), 15 have remained positive (+) all through. These reactions I have grouped as A, B, C.

Amongst the routine questions put to each patient is one to elicit, if possible, the time of infection and date of onset of symptoms, and these two dates have been worked out for the cases falling into the above three groups, and the period of time elapsing between infection and commencement of treatment is shown in the following table.

Group.	A.		B.		C.
Average number of days since infection	70	......	92	......	89
Average number of days from onset of symptoms to starting treatment ...	36	......	66·5	......	65
W.R. at completion of treatment	–	......	±	......	+

From these figures it seems quite clear that in those groups B and C, where the W.R. did not become negative, the time intervals are considerably longer than in group A. One would have expected group C to show the longest time intervals, but in this series such is not the case, and it is possible that the difference between ± and + in these cases is really small. It is interesting to note that the average age of these groups becomes progressively higher, thus: average age, group A, 26·2; B, 28·7; C, 30·8. It is possible that this may eventually be found to have some bearing on the blood reaction and account for the readings in group C; at present, however, the figures are accepted as they stand.

The interval "onset of symptoms to commencement of treatment" is a much more accurately-determined one than "date of infection to commencement of treatment," since the average out-patient dates all events from the various feasts, Easter, Whit-Sunday, and so forth, and the exact date of any particular exposure to infection is generally rather hazy in consequence. In groups B and C this interval is nearly twice that in group A, and seems to render the blood more stable positively (+) and a negative W.R. more difficult to produce.

The cases in Group A all gave a negative W.R. after 81 days' treatment, but of the 34 in this group only 15 have been under observation sufficiently long to note the result of the further test, that is, two months after cessation of active treatment; of these, 7 have remained negative, whilst 8 have become positive again. These groups could be further split up into various classes according to the reactions to the test, but the numbers dealt with are too small to warrant such minutiæ, and only the broad facts shown in the three groupings above are of any value.

Two examples of groups B and C, which may be called the "retarded" groups, may be given as typical records of the way the W.R. behaves under treatment.

Example.

		1		2
First day of treatment.	W.R.	+ + +	......	+ + +
Complete course.				
Last day of treatment.	W.R.	+	......	+ + +
Follow-on course.				
End of F.O.C.* course,	W.R.	–	......	–
Two months' observation.				
End of this period.	W.R.	+	......	±
Second F.O.C.				
End of this course.	W.R.	–	......	–

* Follow-on course (F.O.C. = 0·3, 0·4, 0·6 grms. "606" at fortnightly intervals; 1 gr. Hg intramuscularly weekly).

All these records emphasise the fact that where a long interval has occurred between the onset of symptoms (or date of infection) and commencement of treatment—that is, where a positive W.R. has been long established—the latter can only temporarily be made negative. This opens up the difficult question of whether in late syphilis a positive W.R. reaction should necessitate active antisyphilitic treatment in every case, the answer to which question must be left open for the present. It is extremely difficult to determine the point at which active treatment must cease, and no general rule can as yet be formulated, but one frequently sees patients who have no sign or symptom of disease and who are clinically perfectly fit yet whose W.R. has returned to positive after two months' cessation of treatment. On the strength of such positivity a second full or modified F.O.C. course is given, producing a negative W.R., which, again, often becomes positive after a second period of "no treatment." Should such a patient receive a further course at this stage? Each case must be judged on its own merits, but it seems to me that too much stress can be placed on the W.R. in these cases, and the possibility of a permanent cure with a + W.R. must be kept in mind. It will be some years yet before this question can be definitely answered, and the best one can do at present is to keep the patients as far as possible under observation and on the appearance of any symptoms, however mild, to urge further active treatment.

Summary.

1. Primary cases are still in a grave minority of admissions.
2. Women do not seek advice in the primary stage, and steps should be taken to disseminate knowledge of the dangers of venereal disease and the advantages of the clinics amongst the female population.
3. Continuity of treatment is essential for cure, and discontinuity a possible danger.
4. Only where treatment is commenced before the W.R. has become positive can a cure be definitely promised.

A NOTE ON THE LATER HISTORY OF FOUR CASES OF TOTAL LARYNGECTOMY.

By Sir CHARTERS SYMONDS, K.B.E., C.B.,
CONSULTING SURGEON TO GUY'S HOSPITAL.

THERE are some operations for the removal of malignant disease of the tongue, pharynx, and larynx which leave such a condition of misery that they had better not have been performed. And moreover, if recurrence takes place, the suffering is far greater than if the disease had been left to run its course. This view was at one time taken of complete laryngectomy, against which it was further urged that, unable to speak, reduced, in fact, to dumbness, such a person could neither be useful nor find any joy in life. Experience has happily revised these views, and has shown that a man without his vocal apparatus can not only communicate with his fellows, but conduct a business involving a fair amount of conversation.

The object of the following note is to exhibit, as far as can be done on paper, the condition of four people, three men and one woman, who have lived in comfort and happiness, and done useful work for 8, 12, 15½, and 22 years respectively. One—the woman—has died of old age, and it will be seen that hers was the most extensive of all the operations. The importance, in view of possible recurrence, of estimating before operating the possibility of complete removal cannot be overestimated, especially where the pharynx is concerned. A primary pharyngeal cancer extending to the larynx cannot, in my experience, be removed with any prospect of eradication, and the after-condition is one of such misery as to render all such undertakings unwise and even unjustifiable. Particularly is this the case when a fixed and deep-seated mass of glands complicates the condition.

Record of Cases.

These records have a value also in showing the immunity that can be obtained even when the disease is extensive. These people can be understood of those around them by simple lip-movements and the vibration of such an amount of air as can be taken into the mouth and pharynx, while with the tube presently to be described the patient can be heard in a large room.

CASE 1.—Mrs. G. When seen in 1897 was wearing a tracheal tube and had complete laryngeal obstruction. The growth could be seen fungating upwards through the larynx, and there was also some external fullness. The entire larynx, together with a wide area of the pharynx, both lobes of the thyroid gland, with underlying lymphatics, were removed. On account of the wide removal of the pharynx there was some stenosis which for a time gave rise to difficult deglutition. This improved and she carried on her duties in her hotel for some years. Thyroid extract kept her free from the evil effects of hypothyroidism. Writing to me this year and recording her death at the age of 76, 22 years after operation, her son-in-law tells of her many years of usefulness and the happiness of her life. She was able to converse with her family and friends without any effort, and I have on several occasions spoken with her myself.

CASE 2.—J. B., aged 52, was admitted to Guy's Hospital with a growth nearly filling the larynx; it arose from the left side, and there was also some external fullness. On opening the larynx it was seen that only the anterior part of the right cord was free. On separating the skin from the left side with a view to partial laryngectomy it was found that the disease involved the muscles, and therefore complete removal was decided upon. The left lobe and the thyroid gland, together with subjacent lymphatics and parts of the infiltrated muscles, were removed in July, 1904. The wound healed rapidly without the escape of any saliva. This man, now aged 67, is an assessor and collector of taxes in a large area in Sussex. His duties necessitate a good deal of conversation, and he can make people hear and understand without the speaking-tube, which is necessary, however, when there is much noise or where others are deaf, or, again, when he attends a business meeting. J. B., it will be gathered, holds a responsible public position, and, I may add, is one of the happiest men I have ever met. Some years ago, at one of my clinical lectures, he was able to make everyone in a fairly large theatre hear quite distinctly with the aid of his tube. It is now 15½ years since his operation.

CASE 3.—Mr. McC. was a chemist attached to a commercial firm. In September, 1904, one cord was removed for suspected growth. In January, 1905, an operation was necessary on account of swelling, which proved to be due to some septic sutures. On April 24th, 1911, tracheotomy was performed, and on the 28th the larynx was again opened and some growth removed which was said not to be malignant. Recurrence taking place, tracheotomy became again necessary on June 15th of the same year. The late Sir Barclay Barron sent him to me in July, 1911. As the case appeared from the history to be doubtful, I removed a piece for examination; on this proving to be cancerous, on August 4th I removed the entire larynx, together with the lobe of the thyroid gland and subjacent lymphatics. Healing was by primary union, and the patient returned home on August 26th. A year later, a recurrence taking place in the lymphatics on the left side, on July 19th, 1912, I removed parts of the laryngeal and sterno-mastoid muscles, the internal jugular vein together with the lymphatic track down to the clavicle. From this he recovered rapidly, and returned home on the 27th of the same month. The seven years and more during which this man had laryngeal symptoms indicate the chronic form the growth assumed. He was seen by Sir Henry Butlin and others. The growth when I saw him blocked the larynx, and was of a hard cicatricial variety, partly due no doubt to the effect of the two operations. Reporting upon his speaking on Oct. 21st, 1919, Mr. McC., now aged 63, says that at first he could not sniff up the odours of the chemicals, but this he soon overcame. He says: "I only occasionally use the detachable tube for speaking, for I get along quite intelligibly with my intimate friends without it, while a Belgian friend assured me that on my reading Flemish to him he had not the slightest difficulty in understanding me. In the shops, local post office, &c., where I am known—if the place is quiet—I can do without the tube, and very often, when stopped by strangers asking for information, I unconsciously answer them without the tube, and I am surprised to find that I have been understood apparently quite well. The greatest difficulty I have is in making myself heard in a room where a number of people are talking." It will be gathered that this is a contented and happy man, and is a most useful person besides, for his wife, who suffers from bad health, has been dependent upon his care all these years. It is now eight years since the laryngectomy.

CASE 4.—Mr. T. Before his operation was manager of a bank, and was referred to me by Mr. Charles Heath and Mr. F. G. Harvey, in October, 1907. The growth involved the anterior three-fourths of the right cord and extended forward beyond view. Two years before he lost his voice suddenly for a time, and for a year he had been hoarse and obliged to discontinue his duties. The first laryngeal examination was that made by Mr. Heath. On Oct. 16th, 1907, the thyroid was split and the growth removed. Recurrence ensuing, complete laryngectomy was performed in February, 1908. Writing on Oct. 23rd, 1919, he says he is now 58; he manages shopping and ordinary conversation without the speaking-tube where he is known. In his own house he converses freely with his family, and used to call his children downstairs and also amuse them in his own way. He uses the speaking-tube with strangers. A medical friend who lately saw Mr. T. thinks his powers of speech quite marvellous. Mr. T. was obliged to resign his position, as naturally he could not continue the management of a public concern. Had he possessed a private business he might well have carried on his work. He has helped his wife in the management of a boarding house, and has added to the larder by fishing. It is now 12 years since the laryngectomy.

Remarks.

This brief account is sufficient to show that all the patients have lived in comparative comfort, and have been useful members of the family. The immunity has been largely due, no doubt, to the wide initial removal of structures external to the larynx.

The avoidance of preliminary tracheotomy certainly facilitates the operation, and, moreover, diminishes infection. The technique is also a matter of some importance, and may be described in a later communication.

As to the age at which laryngectomy may be safely undertaken I may add that in September, 1919, with Dr. C. F. Routh, of Southsea, I removed the entire larynx from a lady over 70 years of age. Tracheotomy being imminent for recurrent growth, and her voice almost gone, I thought she would be more comfortable without her larynx than with a necrosing growth, a tracheal tube, and at the same time without a voice. She recovered rapidly without any fistula, and suffered very little shock from the operation.

The Speaking Tube.

The tracheal tube is of large size, slightly conical, and fits the trachea closely; it has no inner tube. It is inserted as soon as the trachea is brought forward at the operation. Fitting into this is the special apparatus for speaking, which has a flap-valve admitting air on inspiration. This valve closes on expiration, the air passing through a tube attached to the upper surface and thence into a rubber tube, by which the stream of air is carried to the lips. A vulcanite piece fits into the distal end of the rubber tube, the end of which is flattened and the orifice narrowed so as to deliver a broad and forcible stream of air. The exit tube, to which the rubber is attached, should have as wide a diameter as possible, and should be a good inch from the shield so as to carry the rubber clear of the chin.

This is the simplest form of apparatus in use, and as will be gathered from the accounts given by the patients, enables them to speak clearly under almost all conditions. My own efforts to introduce a sounding reed into the tube have not been successful. I found the rubber valve of a motor cycle horn answered for a short time. The lips, however, very soon became glued together from the moisture and ceased to act. Those who have not observed the effect produced when the lip movements are made in the air current can hardly appreciate the clearness and loudness of the resulting utterance.

INTRAVENOUS INJECTION OF
TARTAR EMETIC IN GUINEA-WORM INFECTIONS.

BY J. W. S. MACFIE, M.B., CH.B., D.SC. EDIN.,
PATHOLOGIST, WEST AFRICAN MEDICAL STAFF, GOLD COAST.

IT is still the common practice among the natives of West Africa when infected with guinea-worm to wait until the worm protrudes, then seize it and attempt to pull it out. The usual result is that the worm is broken and troublesome abscesses follow which may render the patient unfit for active work for a long time. Sir Patrick Manson[1] has described the sequelæ in a graphic manner, which, as it could hardly be bettered, may be quoted in full.

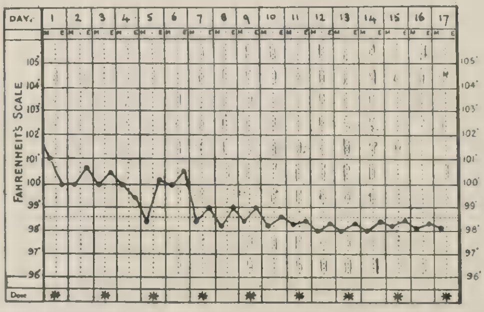
> "The consequences of this accident," he writes, "were often disastrous. Myriads of young escaped from the ruptured ends into the tissues, and violent inflammation and fever, followed by abscess and sloughing, ensued; weeks or months perhaps elapsed before the unhappy victims of this rough surgery were able to get about. Too often serious contractions and ankyloses from loss of tissue and inflammation and even death from septic trouble resulted."

Even if the worm is not broken the process of extracting it is a tedious one; care must be taken to protect it from injury all the time, and the traction should not be begun until the embryos are all discharged, an act which is only completed, according to Manson, in from 15 to 20 days. Any treatment that would kill the worm in situ and the embryos would therefore be valuable.

Record of Cases.

During the last few months of 1919 ten cases of guinea-worm infection in various stages were treated at Accra by means of intravenous injections of tartar emetic. All the patients were natives. I have pleasure in thanking Dr. A. J. R. O'Brien and Dr. M. W. Fraser for very kindly giving the injections to some of the patients, and for permitting me to watch the effects. The following are brief histories of the cases:—

CASE 1.—Native man, aged 20. Guinea-worm of the front of the left leg pointing about half-way between the knee and the ankle. Part of the worm had been pulled out and broken off, leaving the greater part still in the leg. On admission the leg was much swollen and very painful, the guinea-worm sore was suppurating, and the patient was suffering from fever. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, 7th, 9th, 11th, 13th, 15th, and 17th days—a total dose of 9 gr. The temperature of the patient came down to normal on the 7th day. On the 8th day the guinea-worm sore was still discharging slightly, but it healed up a few days later, and on the 17th day the patient was discharged from hospital apparently cured. No pieces of the worm had come away during treatment. Up to the 48th day after the cessation of treatment there had been no recurrence, and the scar where the guinea-worm had pointed remained firm and healthy.



Temperature chart of Case 1. An asterisk denotes each day on which was given an intravenous injection of 1 gr. of tartar emetic.

CASE 2.—Native man, aged 23. Guinea-worm of the left leg near the knee-cap. The head of the worm had just appeared at the opening in the skin. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, 7th, and 8th days—a total dose of 5 gr. The sore healed six days after the first injection, and the patient was discharged from hospital on the 9th day apparently cured. The worm did not come away. The patient, still apparently quite well, left Accra a fortnight later. A month (30 days) after the cessation of treatment he was seen at Koforidua, to which town he had been traced, by Dr. F. H. Storey, who very kindly sought him out and examined him for me. At this time the leg appeared to be perfectly sound, the guinea-worm scar was firmly healed, and no sign of the worm had been seen since leaving hospital.

CASE 3.—Native man, aged 30. Guinea-worm of the outer side of the left foot. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, 7th, 9th, and 11th days—a total dose of 6 gr. On the 10th day the sore appeared to be healing, but a week later it reopened, and living embryos were found in the discharge. Three days later the worm protruded from the sore and was secured; it was slowly wound out during the nine days following. In this case the treatment with antimony did not appear to have any beneficial action.

CASE 4.—Native man, aged 24. Guinea-worm of the calf of the right leg. Leg much swollen down to the ankle. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, and 8th days—a total dose of 4 gr. Already on the 3rd day the swelling of the leg had subsided considerably. The sore was healed by the 9th day, when the patient was discharged apparently cured. The guinea-worm did not come away. A week later (eight days after cessation of treatment) the patient was seen again; the guinea-worm scar was to all appearances soundly healed. Unfortunately, the man left Accra soon after this and was not seen at a later date.

CASE 5.—Native boy, age 15. Guinea-worm of the right leg, on the outer side of the calf. The presence of the worm had been observed two weeks earlier, but the sore had begun to discharge only on the day he was first seen. The discharge contained living embryos, but the guinea-worm itself was not visible. Intravenous injections of tartar emetic were given on the 1st, 3rd, 5th, 7th, 8th, and 10th days, $\frac{1}{2}$ gr. on the first occasion and 1 gr. thereafter—a total dose of $5\frac{1}{2}$ gr. On the 5th day the worm protruded, and the boy pulled out and broke off about 8 in. of it, leaving the rest of the worm in the leg. No abscess formed as a result of this unwise action, but the discharge continued until the 10th day, when it was very slight in amount and contained only a few motionless embryos. On the 13th day the sore appeared to have healed and a week later was in the same condition. Three weeks (21 days) after the cessation of treatment the scar appeared to be soundly healed.

CASE 6.—Native man, aged 47. Guinea-worm of the left leg, half-way between the heel and the middle of the calf. Two weeks earlier the worm had protruded, and a small piece of it had been pulled out and broken off, leaving the remainder still in the leg. When first seen the sore was granulating and discharging a watery fluid, in which, however, no embryos were found. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 4th, 6th, 8th, 10th, and 12th days—a total dose of 6 gr. The sore dried up in three or four days, and appeared to be completely healed on the 14th day, when the patient was discharged from hospital. When last seen, 12 days after the cessation of treatment, the scar appeared to be soundly healed.

---

[1] Tropical Diseases, sixth edition, p. 775.

CASE 7.—Native man, aged 30. Guinea-worm of the outer side of the left foot. The worm, which had first shown itself nine days earlier, was pulled out on the day the patient was seen, and about 3 in. of it broken off, the remainder being left in the leg. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, 7th, 9th, and 11th days—a total dose of 6 gr. The case was complicated by an abscess near the heel of the foot, which had to be opened on the 5th day. On the 7th day a guinea-worm (not the same one as had pointed on the outer side of the foot) appeared in the incision made into the abscess cavity; this worm was wound out. The original guinea-worm sore was almost closed on the 9th day, but on the 14th day about 5 in. of the worm came away, and the sore was not completely healed over until the 19th day. Six days later—that is, 14 days after the cessation of treatment—the sore appeared to be soundly healed.

CASE 8.—Native boy, aged 18. Guinea-worm of the outer side of the left foot. The worm had first appeared four days earlier; none of it had come away. The discharge from the sore contained living embryos. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 5th, and 7th days—a total dose of 4 gr. After the fourth injection the boy ceased to attend for treatment, and it was found that he had left Accra and could not be traced. The ultimate effect of the treatment is therefore unknown, though he appeared to be doing well.

CASE 9.—Native man, aged 30. Guinea-worm of the inner side of the right foot. The foot was swollen and appeared to be forming an abscess; the sore was not open. A month earlier about 1 in. of the worm had been pulled out and broken off, and two weeks ago about 8 in. of it had been similarly removed. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, and 5th days, and on the 9th day, owing to a mistake, ½ gr.—a total dose of only 3½ gr. Almost immediately after the treatment was started the foot began to improve, and by the 10th day it appeared to be cured. When last seen, on the 13th day after cessation of treatment, the foot appeared to be sound.

CASE 10.—Native woman, aged 22. Guinea-worm of the inner aspect of the right foot, close to the ball of the great toe. The foot was much swollen and very painful. The worm had first appeared a week earlier, and 2 in. of it had been pulled out and broken off. The sore was discharging purulent matter. Intravenous injections of tartar emetic, 1 gr. each, were given on the 1st, 3rd, 6th, and 8th days—a total dose of 4 gr. Further treatment could not be given because the patient went away on the 9th day and was not seen again. At the time of the last injection the condition of the foot had improved considerably and the guinea-worm sore was almost closed.

Remarks.

In five of the ten cases the whole guinea-worm was still in the body at the time when treatment was begun. In two (Cases 2 and 4) the sore healed under treatment, and the worm did not come away; one of these cases was seen a month and one a week after the cessation of treatment, and appeared to be cured. In one (Case 5) part of the worm was pulled out and broken off during treatment; this case, nevertheless, did well and was apparently cured. In one (Case 3) the sore closed temporarily, but reopened, and the worm was eventually wound out. One (Case 8) was lost sight of at an early stage.

In five of the cases part of the guinea-worm had been pulled out and broken off before treatment was begun; all these cases showed signs of acute inflammation of the affected limb. The inflammation subsided and the guinea-worm sore healed in three of these cases—1, 6, and 9—the portions of the worm which had not been pulled out remaining in the body but causing no inconvenience. One (Case 7) was complicated by the presence of a suppurating wound, so that the effect of treatment was not clear. And one (Case 10) was lost sight of at an early stage.

In all but one (Case 3) of the cases treated intravenous injections of tartar emetic, even in the small doses given (3½ to 9 gr.), appeared to have a beneficial action. They appeared to relieve the inflammation caused by the breaking of the worm, to effect the healing of the sore without the previous removal of the worm, and to shorten the duration of the affection. In most of the cases it was impossible to continue the injections as long as had been intended, either because the patients had left Accra or because they themselves had concluded, perhaps prematurely, that they were cured and in no need of further treatment. In the cases which were longest under observation it appeared as if the antimony had killed the guinea-worm in the body and allowed it to be absorbed. If this was actually the case the treatment would also, it may be hoped, kill guinea-worms which had not yet reached the surface. This would be an important property, as patients often develop a succession of worms.

Conclusion.

The observations recorded here fall very far short of a thorough test of the treatment. The total number of cases is exceedingly small, the appropriate dose of antimony has not yet been determined, and in the important matter of after-treatment observation they are conspicuously defective.

Accra is provided with an excellent pipe-borne water-supply, and guinea-worms are fortunately rare. The ten cases dealt with were collected one by one, only with the greatest difficulty. The occasional cases that are met with at Accra are, for the most part, in strangers and visitors to the town. Such patients are unsuitable subjects for the trial of a new treatment, because their attendance is irregular, and they can seldom be kept under observation after they are apparently cured. There are many more suitable places for the study of guinea-worm infections, and I can only hope that the observations recorded in this paper may lead to a full investigation in them of the therapeutic value of antimony.

The Laboratory, Accra.

A CASE OF
ABNORMAL DESCENT OF THE TESTICLE.

BY JOHN A. C. MACEWEN, M.B., C.M. GLASG.,
SURGEON TO THE GLASGOW DISTRICT HOSPITALS; HONORARY SURGEON, ERSKINE HOSPITAL FOR THE LIMBLESS; ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY.

THE following case, in which the testicle descended through the crural canal into the scrotum, the inguinal canal being absent and a bubonocele complicating the picture, is interesting in that I have not been able to find reference to a similar one in the literature at my disposal.

The patient, a well-developed boy of 2, was admitted to Mr. T. Kay's wards in the Royal Infirmary suffering from threatened strangulation of a right bubonocele. The bowel slipped back without manipulation after admission, and I operated on Dec. 13th with a view to performing an ordinary radical cure of an inguinal hernia. Mr. Kay, who kindly gives me permission to report the case, had been operating on another patient, but saw the condition, and Dr. J. Dunbar, who was assisting me, confirmed the various points.

On exposing the external oblique the external ring could not be made out, and the cord was therefore picked up and isolated, when it was found to run into the abdomen through an aperture which did not admit the little finger. This aperture was situated below Poupart's ligament, and to the outer side of the spine of the pubes. The tip of the little finger, inserted with difficulty at a later stage, made out what appeared to be Gimbernat's ligament to the inner side, but it did not present the usual sharp margin. Below was the bone, covered with fascia, while on the outer side was a firm structure which was probably a misplaced reflexion from Poupart to the pubes, described in some books as separating the muscular from the vascular compartment—the ilio-pectineal band.

On applying gentle traction on the cord the scrotum became invaginated and the testicle came into view. The testicle was normal, and its attachment to the base of the scrotum undoubted. The hernial sac lay among the structures of the cord, and the vas was adherent to but separable from it. As the sac terminated about half an inch above the testicle the hernia was not of a congenital or infantile type. On opening the sac a soft yellow mass was found projecting into its interior, and springing from the outer and posterior wall of the sac. As its surface was glossy it was apparently covered with peritoneum, and it appeared to be embedded in the sac wall. Traction failed to bring this structure down to any appreciable extent, and hence its nature and connexions could not be determined. As it was not adherent to the tissues outside the sac, and presented no obstacle to introduction of the sac as a pad on the deep surface of Poupart, further examination was deemed inadmissible. I have seen a similar structure in the sac of a sliding hernia, and it is probable that the termination of the appendix or cæcum was close at hand, but this is surmise, as these parts were looked for but not found. If it was a portion of the plica vascularis it was separated entirely from the testicle, and terminated about one and a half inches above it.

The conjoined tendon was closely applied to the posterior surface of the external oblique and came down to, and appeared to fuse with, Poupart's ligament. There was no arching of the fibres of the conjoined, such as is normally present, and hence the transversalis fascia was not exposed to view.

The operation as such presented no points of special interest, and the patient is doing well. The testicle on the left side was very small, and was situated about the upper end of the scrotum. It was difficult to determine the route taken by the cord, but the femoral ring was certainly unduly large.

The condition here reported is apparently a very rare one, as Eccles, in his "Imperfect Descent of the Testicle," 1903, says: "Recent dissections during a radical operation upon the accompanying hernia have not shown the cord lying in the femoral ring, but always in the superficial abdominal ring."

SYPHILITIC SPONDYLITIS:

NEGATIVE WASSERMANN REACTION.

By S. C. EVANS, CH.M. EDIN.,
LIEUTENANT-COLONEL, I.M.S.;
AND
C. F. MARSHALL, M.D. VICT., F.R.C.S. ENG.

SYPHILITIC spondylitis is a rare condition. Verneuil[1] appears to have been the first to draw attention to it in 1879, and Fournier[2] the first to describe a case in detail about the same time. Previous cases were probably regarded as tuberculous. In Fournier's case the lumbar vertebræ were affected, the patient died of cachexia and general dropsy, and the lesions found at the autopsy were as follows: Sclerosing osteitis with purulent and caseous infiltration, almost complete destruction of one of the intervertebral cartilages, a large cavity in the lumbar spine, double psoas abscess, a gumma in the fourth left lumbar nerve, and atrophy of the gluteal muscles. The patient also had multiple gummas in the subcutaneous tissue and muscles, syphilitic orchitis, and cirrhosis of the liver and kidneys.

The case we report resembles Fournier's in affecting the same vertebræ, but differs in the absence of cavitation of the vertebræ, abscess formation, and muscular atrophy. In our case the process of new bone formation predominated over bony destruction. This is characteristic of most cases of syphilitic spondylitis and distinguishes them from tuberculous disease.

The patient, a man now aged 38, contracted syphilis in 1905. Treatment by oral administration of mercury was commenced during the primary period and continued for two years. Secondary symptoms were absent except for mild sore-throat. In 1911 he went through a six months' course of treatment, consisting of weekly injections of mercurial cream and iodide of potassium in doses of 15 up to 60 gr. daily as a precautionary measure previous to marriage, although no symptoms had occurred since 1905. In 1914 he began to suffer from pain and stiffness in the back, which was diagnosed as lumbago. As this did not improve with ordinary treatment, a Wassermann test was made, and this was negative. In 1916 the lumbar pain became worse, especially on rising from a sitting position, and he complained of pain down the left thigh. At this time nodes developed on the inner end of the right clavicle and on the inner malleolus of the right ankle, and he suffered from severe headaches, mental irritability, and insomnia. Except for the node on the clavicle, which persisted, all these symptoms yielded to treatment with large doses of iodide of potassium and mercurial inunction.

The Wassermann reaction in 1917 was again negative. He then had a course of six intravenous injections of salvarsan at monthly intervals, after which his general health improved and the lumbar pain disappeared.

However, after the fourth salvarsan injection he had sudden acute pain in the right loin resembling renal colic. A radiogram taken at this time was negative for renal calculus, but revealed lesions of the lumbar spine consisting of pronounced bulging of the outline at the level of the second and third lumbar vertebræ on the right side and at the level of the third and fourth vertebræ on the left side. These swellings were due to new bone formation on each side of the intervertebral cartilages, the contiguous vertebræ being thereby united by bony deposit bridging over the cartilages, thus accounting for the rigidity of the lumbar spine.

The present condition is as follows: General health good, although there is some thickening of the radial arteries. The lumbar spine is quite rigid, but painless. Remains of node on clavicle still present. Reflexes normal. No paresis or atrophy of muscles. Wassermann reaction negative.

Remarks.

Noteworthy features of this case are the rarity of the lesion, its occurrence in spite of treatment, and the persistently negative Wassermann reaction, the first test being made when the vertebral lesions were in active development. All tests were made at reliable institutions, the first and second in Government laboratories in India and the third in a well-known London hospital. This case would therefore appear to serve as a warning against placing too much reliance on the Wassermann reaction, both as regards diagnosis and prognosis.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

EXHIBITION OF CASES.

A MEETING of this section of the Royal Society of Medicine was held on March 12th, Sir ANTHONY BOWLBY, the President, being in the chair.

Traumatic Aneurysmal Varix.

Dr. W. G. SPENCER showed a case of Traumatic Aneurysmal Varix between the Cavernous Sinus and the End of the Internal Carotid Artery on the Left Side. The patient, aged 26, whilst on duty in France, was kicked by a horse on the left side of the head in February, 1918. He was unconscious for a time, but did not bleed from his ear or nose. After recovering consciousness he continued mentally dull, occasionally vomited, and complained of headache. Two weeks later clear fluid under excess of pressure was drawn off by lumbar puncture. Increasing œdema of the eyelids was noted early in March and he was transferred to hospital with the diagnosis of fractured base of the skull. No sign of fracture could be found by X ray examination. The most obvious features were venous engorgement of both upper eyelids, especially the left, and proptosis, which was also most marked on the left side. There were chemosis of the ocular conjunctiva of the left eye and paralysis of the left external rectus. The man complained of a continuous rushing noise in the head on the left side. A loud systolic souffle was heard over the forehead; it was loudest over the upper eyelids and eyeballs, but could be heard more faintly over the left temporal region, the face, and along the line of the carotid in the neck. When the left carotid was compressed the souffle was not heard.

The left common carotid was ligatured at the level of the cricoid cartilage seven weeks after the accident. On tightening the ligature the souffle disappeared, but was soon heard again at the root of the nose and more faintly over the upper eyelids. The venous engorgement of the eyelids rapidly diminished. There was no optic neuritis, but complete and permanent paralysis of the left external rectus. Afterwards he was unable to do more than light work. Headaches were very variable. The rushing noise gradually returned; when he pressed his left eyeball outwards the noise seemed to stop for a moment. When admitted to hospital at the beginning of the year the souffle was heard at the root of the nose and less loudly over the forehead. It could also be heard, more faintly, in the right infra-orbital region, but not over the left temporal and facial region as before the first operation.

The right carotid artery was ligatured in January, 22½ months after the left. Before tightening the ligature his head was lowered to the level of the trunk, and he was let out somewhat from the anæsthetic. The tightening of the ligatures caused deep anæsthesia, with stertorous breathing and contracted pupils. He was kept in bed with the head horizontal; he fainted several times when being moved or dressed, and did not get up for six weeks. Since the second operation he had not heard a noise unless his head was sideways on the pillow. He complained of headache at irregular times and the usual remedies did not relieve him.

Mr. Spencer said that he presumed that in this case there was a pinhole communication between the left cavernous sinus and the dilated end of the left internal carotid. The anterior communicating and the intracranial part of the ophthalmic arteries might also be dilated. There was no positive sign of any aneurysmal sac formation, apart from the arterial dilatation, nor any sign of thrombosis of the cavernous sinus. He hoped that the bilateral ligation would control a tendency to further dilatation; the most marked effect had been the relief to compression of the left cavernous sinus.

The PRESIDENT said that it was difficult to make a prognosis in such cases, for some got well, others remained in statu quo, and others got worse. He instanced the case of a man, wounded in the region of the zygoma in the South African war, who applied for treatment on account of the intensity of the noise in his head. As the result of keeping him quiet in bed in the course of a month or two he was so much better that he no longer desired an operation. Gradual recovery resulted in a spontaneous cure in about two years. In another instance a man who had been riding a bicycle was found unconscious on the road at some distance from his bicycle. He remained unconscious for several days. In his case, also, the condition often termed pulsating exophthalmos developed. He was an elderly man with thickened arteries, and operation seemed inadvisable. He also got perfectly well in two years. There was no doubt that in young people an operation was indicated to cure the patient. This was clearly so in Mr. Spencer's case, whom he congratulated upon its success.

Microcephalia: Craniotomy Performed.

Mr. SPENCER also showed Two Microcephalic Sisters, the children of first cousins, shortly after craniotomy. The parents were both healthy, aged between 20 and 25, and except that they were first cousins there was nothing in their family history which bore on the condition of their children. They were anxious that something should be tried, and Mr. Spencer, at their request, after a consideration of Horsley's first case, decided to operate. The children, one aged 3 years and the other 1½ years, were in good general health. Except for the calvarium, deficient hair, and general dwarfing, they presented no deformity. They had all their teeth, and these were practically perfect. The development of the calvarium had been arrested so as to give them the repellant aspect of anthropoid apes. The elder was unable to walk more than a few steps; she could not feed herself, was dirty in her habits, could say nothing except "Bad"; could only sit up, toss her arms, and fumble with toys, and did not otherwise amuse herself; had violent fits of temper, in which she bit herself and threw herself backwards so as to strike the back of her head. Her hair was very scanty. The younger child was unable to walk or stand, could only say "Bad" and "Mum," was dirty in her habits, did not play or amuse herself but merely tossed her arms, was uncertain in temper and unable to feed herself, had no idea of obedience, and had no hair on her head. The operation was performed on the older child at one sitting and caused no perceptible shock. On the younger child it was done in two stages at a fortnight's interval. There was little shock after the first and more after the second. At the operation a strip of bone about 3 cm. in breadth was removed from each parietal bone, and a strip about 1 cm. in width from the frontal bone a little in front of the coronal suture. Both skulls were thin, like those of a baby under a year. The lines of the sutures were occupied by ridges of soft bone. There was nothing abnormal about the exposed dura mater. The intracranial pressure was not above normal. The children were now in the same condition as before the operation; the gaps made in the skull showed no signs of intracranial tension. In the region of the left parietal eminence of the younger child the brain could be felt protruding and pulsating under the scalp.

Hysterical Manifestations.

Dr. HILDRED CARLILL showed a young woman with Hysterical Manifestations in the Eye and Stomach. There was a history of "vomiting" since 1915 and after every meal for nine months. For three months she had noticed that her eyes were insensitive. The "vomiting" was regurgitation merely, unaccompanied by the usual signs of vomiting, and could be produced at will. When seen for the first time the ocular conjunctivæ were insensitive, as was the corneal conjunctiva in one eye; the palpebral conjunctivæ were also insensitive. The corneal reflex was present.

Dr. F. PARKES WEBER said that he regarded the case as an example of acquired merycism or human rumination. The patient had acquired the power of bringing food from the stomach back into the mouth, and could then either swallow it again or expel it. If she expelled it the act constituted a kind of "voluntary vomiting," which she could make use of to excite sympathy or interest in her case. (Dr. Carlill had said that she had likewise produced artificial skin trouble on her legs.) With regard to the eyes, he (Dr. Parkes Weber) had found that she closed the eyelids sharply when he touched the corneal conjunctiva.

SECTION OF SURGERY: SUBSECTION OF ORTHOPÆDICS.

Exhibition of Cases.

A MEETING of this section of the Royal Society of Medicine was held on March 2nd, Mr. J. Muirhead Little, the President, being in the chair, when cases were exhibited.

Osteosclerosis of the Femur.

Mr. Laming Evans showed a case of Osteosclerosis of the Femur in a man aged 34. He had had pain in the left hip, thigh, and knee since September, 1916, which had continued without intermission. He had been treated by hot air, electricity, and baths both in London and at Buxton for 18 months. Six injections of salvarsan had been given on the chance that the case was syphilitic, although a Wassermann test had always proved negative. He complained of continuous pain in the left thigh both by day and night, for which slight relief was afforded by very large doses of aspirin. The left thigh showed three-quarters of an inch of atrophy as compared with the right. A slight thickening of the left femur could be felt at the junction of the upper and middle thirds. Local heat, redness, or swelling of the soft parts was absent. X ray examination showed an osteosclerosis of the shaft of the femur involving the whole circumference of the shaft, but more marked upon the median segment, and extending through the middle and upper thirds as far as the lesser trochanter. The outlines of the sclerosed bone were smooth and the internal structure was well defined. The medullary canal was not encroached upon, and there was no evidence of necrosis or chronic abscess. The treatment suggested was exposure of the femur on its median surface, and a longitudinal linear osteotomy exposing the medullary cavity throughout the length of the sclerosed area.

New Growth Formation.

Mr. Evans also showed the X ray photographs of the left thigh of a man, aged 43, who had complained of pain in this position in February, 1919, together with swelling, which started just above the left knee and had gradually increased in circumference and spread upwards. Old-standing scars in the region of the right iliac bone suggested osteomyelitis in infancy. The right hip-joint was freely movable. In January, 1920, when he came under observation, he said that he had lost 6 st. in the preceding 12 months. The left thigh showed a hard fusiform enlargement in the lower three-fourths, involving the femur. X ray examination showed a fusiform thickening of the middle third of the femur, with spicules of bone projecting obliquely from the shaft. In February an incision on the inner side of the middle of the thigh exposed a cavity containing semi-solid gelatinous material. At the bottom of the cavity the periosteum was thickened and studded with bony spicules. An incision on the outer side of the thigh exposed a growth formation three-quarters of an inch thick attached to, and growing from, the periosteum. A section of this growth was shown. A report of the semi-solid material stated that a few streptococci and staphylococci were found, but the specimen was almost sterile. The tissue cells present were almost entirely lymphocytes, together with a few endothelial cells. The specimen appeared to be an inflammatory exudate.

Mr. R. C. Elmslie said that there were three points which made him think that the case was not one of sarcoma: (1) in the microscopic section there was no evidence of the presence of sarcomatous tissue, but only the signs of infiltration and chronic inflammation; (2) in one skiagram there was definite curvature of the femur; and (3) in one there was an appearance suggestive of the presence of a long sequestrum. He thought the condition was one of chronic osteomyelitis, and that, for some reason, the periosteum had taken on the spiky form associated with sarcoma.

Mr. V. Warren Low agreed as to the probable presence of a sequestrum.

Achondroplasia in a Girl.

Dr. W. T. Gordon Pugh showed a case of Achondroplasia in a girl, aged 7 years, who was 35½ in. high, the height of a child of 3½ years. She presented the characteristics usually found—the stunted arms and legs contrasting with a trunk of normal length, the short fat "trident" hand with digits all nearly of the same length and showing the deviation of the ring from the middle finger, and the dorso-lumbar kyphosis closely resembling that found in rickets. The clavicles, sternum, and ribs were, as usual, unaffected; the child was bright and fairly intelligent; skin, hair, and thyroid appeared normal, and the Wassermann reaction was negative. The stunted bones of the limbs had broad ends, the shafts were not abnormally bent, and there was full movement of all joints except the elbows. These joints could not be fully extended by about 30°, and there was cubitus valgus, the deviation outwards of the forearms being about 35°. Her measurements in inches, as compared with those (in brackets) of a control child of the same age, were: height, 35½ (43); from the base of skull to infragluteal fold, 19½ (19½); from infragluteal fold to sole, 10 (19½); from acromion to tip of fingers, 13 (19½); humerus, 5 (7¾); ulna, 5 (6¼); femur, 6 (10½); tibia, 5¼ (9¼); between anterior superior spines, 6 (6¼); girth of skull 21 (20). X ray photographs showed that the bone in the epiphyses was less than normal, whilst the diaphyses showed a slight cupping indicating that the periosteal bone had not been completed by the addition of enchondral bone, which the epiphyses normally deposits at the end of the diaphyses. The ætiology of the condition appeared to be still unsettled. By some it had been thought to be simply a biological variation similar to that which exists in certain breeds of dogs. It had been suggested that it might be due to under-secretion by the pituitary, thyroid, and thymus, and over-secretion by the interstitial glands. Jansen, of Leiden, eight years ago, produced evidence that this disturbance in the development of the skeleton might have resulted from pressure on the fœtus at a very early period, from the third to the sixth week, by an amnion, either too small or over-distended with fluid. In respect of treatment he suggested that, having regard to the fact that the pituitary body had been found reduced in size in severe cases, the prolonged administration of small doses of pituitary gland might possibly stimulate growth, although it would never cure the achondroplasia. He did not know whether this had been tried. Recently Professor Arthur Keith had declared that although experiments on the thyroid had failed to produce achondroplasia, and microscopical examination had revealed no change in the thyroid gland, these cases might safely be grouped as a growth disturbance due mainly to alteration in some of the functions of the thyroid body. It was generally agreed, however, that thyroid medication had no influence on their growth.

Exostosis of the Radius.

Dr. Pugh also showed a case of Exostosis of the Radius in a boy aged 15 years, the exostosis being about an inch and a half wide and raised about half an inch, arising from the lower end of the radius just above the epiphyseal line. The boy said that he had noticed it about two years and thought that it had grown recently, especially since he knocked it a few weeks ago. It gave him no trouble at present, but as he wished to enter the navy it would probably be advisable to remove it.

Mid-carpal Fracture Dislocation.

Mr. R. C. Elmslie showed a case of Mid-carpal Fracture Dislocation in a man, aged 38, who had had an accident to his left hand in January, 1916. He was in the hold of a ship, and a heavy sling swung against him, threatening to pin him against the side of the hold. He protected himself by holding out his hands and knee. The sling forced the left wrist into a hyperextended position. The condition was treated in a military hospital as a fracture. The hand recovered to a certain extent, but the condition had for a long time been stationary. The styloid processes were at the normal level: on the posterior surface of the wrist the ends of the forearm bones were less prominent than on the right side, and the posterior surface of the carpus was more prominent. The wrist was usually held in a straight line with the forearm, and only about 30° of flexion, and no extension was possible from this; no abduction or adduction was possible. X rays showed a fracture of the scaphoid and semilunar, one-half of the scaphoid remaining in apposition with the radius; the rest of the carpus was dislocated backwards. The styloid processes of both radius and ulna had been fractured. He proposed to remove half of the scaphoid fractured and the semilunar.

Cyst of the Tibia.

Mr. ELMSLIE also showed a case of Cyst of the Tibia in a boy aged 10 years. About a year ago the patient fell, striking the left knee on the ground. He walked home, and the same night a swelling appeared which implicated the whole of the knee, accompanied by much pain. A week later he was seen by a doctor, who put on a bandage. The patient was not confined to bed at all. After the application of the bandage the swelling decreased, but had never disappeared. There had been some pain ever since, but no hindrance to walking, except when he had been using the legs for some time. The boy was healthy, and had always been so. There were a few palpable glands in the neck. There was no wasting of the lower limbs, and the reflexes were normal. In the left knee region there was a rounded, hard, semi-spherical swelling 2 in. in diameter, situated on the internal surface of the head of the tibia. The skin moved freely over it, and there were no signs of inflammation. At present there appeared to be no implication of the knee-joint. There was no limitation of movements, no tenderness, no shortening, and no other abnormal bony condition. He proposed to open the cavity, curette it, and crush the wall.—In answer to a question by Mr. P. B. ROTH, Mr. Elmslie said that in cases of cysts of the femur, humerus, and tibia upon which he had operated healing had taken place satisfactorily, the bone around had sclerosed, but a slight cystic appearance had remained for years. In no case was there further growth or expansion or recurrence. Pain was relieved.

Mr. ELMSLIE also showed a case of Congenital Absence of the Tibiæ in a girl aged 13 years and 8 months. The deformity was congenital, and no treatment had so far been carried out. The tibia was absent in both the lower limbs, the patella and the condyles of the femur being apparently normal. The head of the fibula on either side was large and articulated with the outer side of the external condyle. The feet were in severe talipes varus; on the right there were four toes, with a deep cleft between the first and second, as in a lobster-claw deformity. On the left side the great toe was absent. The child got about well on the knees. He proposed to amputate at the knee on each side, and would present a further report on the anatomy of the parts removed at a later meeting.

Mr. ELMSLIE also showed a case of Birth Palsy with Dislocation of the Head of the Radius. The patient, a girl aged 15½ years, had a deformity of her right arm since birth. She had been born in hospital and both arms were said to have been injured. No treatment appeared to have been carried out. The arm was held a little away from the side, with the elbow flexed and the forearm supinated. Movements of abduction and rotation at the shoulder were restricted. Full extension of the elbow was impossible, and pronation of the forearm was also absent. Active use was present in all the muscles of the limb except the pronator radii teres, but the deltoid, triceps, and extensors of the wrist and fingers were weak. The muscles all reacted to a faradic current, including the pronator radii teres. An X ray photograph showed a forward subluxation of the head of the radius and a great prominence in front of the tuberosity. The chief interest of the case consisted in the supination deformity and in the presence of the subluxation of the head of the radius. He did not think that excision of the head of the radius was advisable, as it would probably weaken the arm, and the girl got very good use out of the hand with the condition as at present. He proposed to limit treatment to manipulation and exercises for the joints and electrical treatment of the weakened muscles.

After referring to the rarity of supinator birth deformity, Mr. Elmslie said that it was probably due in this case to subluxation of the head of the radius and a consequent tightening of the biceps muscle, which held the head of the radius in that position during growth. It was not due to any weakness of the pronator radii teres.

A Case for Diagnosis.

Mr. P. B. ROTH showed a case for diagnosis. It was that of a boy, aged 4 years, with waddling gait. He had never walked properly, but always with the toes turned out, rocking from side to side with each step. He had previously been treated for a time with long external splints, but these had not been able to keep the legs from turning. He had suffered from rickets, as evidenced by slightly curved tibiæ and enlarged lower radial epiphyses. The gait was characteristic of double congenital dislocation of the hip, but the radiogram showed no abnormality of outline of bones to suggest this condition. When lying supine abduction of each thigh was limited to 45°. The thighs were kept rotated out 80°, but could be turned so as to make the toes point straight up, using moderate force. Mr. Roth said that he had since been informed by Dr. Martin Berry that in all probability this was a case of torsion of the femoral shaft.

Dupuytren's Contraction.

Mr. ROTH also gave a report on the case of Dupuytren's Contraction in a man, aged 31, whom he had shown before the section in November last. The ring finger of the left hand was the finger involved. He had operated on him by Adams's subcutaneous method. Under chloroform eight or nine punctures were made into proximal parts of the tense fascia with a fine tenotome, and the fascia divided at each part by turning the blade of the tenotome down into the palm. Traction was simultaneously made on the flexed finger, and, as each part was divided, the finger gradually straightened until it lay completely extended. A straight splint was applied and kept on for a week, after which it was removed during the day, but applied for a further two weeks at night. The result had been a complete cure, with full power of extension and flexion.

SECTION OF OPHTHALMOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

An ordinary meeting of this section was held on March 3rd, Mr. W. T. HOLMES SPICER, the President, being in the chair.

Iridotomy.

Mr. J. HERBERT PARSONS showed a patient who last year came up for extraction of an immature cataract; the opacity was chiefly in the posterior cortex. He did an ordinary extraction, with a peripheral button-hole, and a tiny hole in the periphery of the iris afterwards. The patient did well, and went out in ten days with the eye quiet. A week later, however, she came with a hypopyon and a flaring iritis, which he attributed to endogenous inflammation. He took her in and treated her in the ordinary way, and the pupil became very small, in spite of atropine and hot bathing, and was later completely blocked. He described the method of iridotomy he carried out.—Mr. M. S. MAYOU confirmed Mr. Parsons's account. He first saw the operation done by Mr. McHardy many years ago.

The PRESIDENT and Mr. TREACHER COLLINS had also performed the operation.

Sensitive Vestibular Nystagmus.

Mr. LESLIE PATON exhibited a patient in whom Nystagmus of Vestibular Origin was very easily excited —namely, by pressing wool into her ear. A fistula existed from the vestibular region into the middle ear. She had choroiditis and other visual defects, but he did not bring her because of those. He also showed a patient with Blue-dotted Cataracts. In cases of this kind which had been reported the vision was but little interfered with, and the ophthalmoscope showed that not much opacity was evident. With correction this patient's vision was 6/12 in one eye and 6/9 in the other. Probably the blue tinge was not due to the presence of pigment, but to a refraction peculiarity. He quoted Lord Rayleigh's explanation.—Mr. C. Wray said he had seen several cases in parents and children. —Mr. N. Bishop Harman spoke of cases in which the presence of such blue striæ and dots was associated with night-blindness.

Mr. M. S. Mayou showed a case of Gummata of the Eyelid which began on the tarsus. The erosion of the eyelid had been quite rapid, and could be seen to progress even while she was awaiting the Wassermann report. Salvarsan had produced great improvement in a short time.

Mr. W. H. McMullen exhibited a case of Congenital Aniridia. He brought it forward because it was associated with some signs of glaucoma. It was very difficult to see the discs, but they appeared to be cupped, and on palpation the ocular tension seemed to be increased. He asked for views as to the operation most suitable.—Some speakers favoured cyclo-dialysis in preference to trephining.

Mr. McMullen also showed a case of Translucent Cyst in the outer part of the orbital margin, firmly adherent to the roof of the orbit and loosely attached to the tarsus.

Sir William Lister referred to an interesting case of his own in which a cyst of the lacrymal gland went behind the globe. The patient, a boy, came with proptosis of the left eye, which became worse and pushed the eye downwards and inwards. He did Kronlein's operation, and having removed the triangular portion of bone he made a horizontal incision through the periosteum, and, having separated the orbital fat, encountered a very black tumour. He was proceeding to separate this when it suddenly burst and the contents disappeared. It was mixed up with the lacrymal gland and the external rectus. Healing occurred by first intention, and the vision, which had gone down to 6/24 with marked papillœdema, returned to 6/6, and there was only slight contraction of the field remaining.—Mr. Wray suggested that dissection would be much easier if part of the cyst contents were evacuated by preliminary puncture and then a ligature passed round it.—Mr. H. R. Jeremy referred to a case in which he removed a cyst from the inner side of the upper lid, and the microscopist found it was lined with squamous epithelium. He regarded it as a transplantation cyst, and suggested that that might be the nature of Mr. McMullen's case.—Mr. Leslie Paton said Mr. Jeremy removed a cyst of Krause's gland, and in such cases it was not advisable to puncture before removal if it could be got away without.

Cards for Testing Colour Vision.

Dr. F. W. Edridge-Green showed, by means of the epidiascope, a set of cards for testing varieties of colour vision by natural light. The set contained neither letters, figures, nor any easily identifiable geometric form to assist any candidate who wished to escape the test. The exhibitor explained fully the scheme for detecting trichromics, tetrachromics, and pentachromics.—Mr. Parsons said that the scheme was most ingenious, but pointed out how difficult it had always been to ensure, in printed colour-test charts, that successive editions, or even separate copies, should contain exactly identical shades of colour, owing to the pigment changes in the lithographic stone.

Cobalt Glass for Detecting Errors of Refraction.

Mr. Paton read a short note on the Use of Cobalt Glass for the Detection of Errors of Refraction, especially small degrees of astigmatism. He demonstrated its use.—Mr. Ernest Clarke, while agreeing that this particular kind of glass showed that the violet rays were more refracted than the red, did not think it filled any very practical purpose for the ophthalmologist.—Mr. Bishop Harman agreed with Mr. Clarke, and thought that the introduction of this kind of glass would cause some sensitive patients to worry needlessly over trivial astigmatic errors.

Mr. Charles Goulden read a paper on the Treatment of Prolapse of the Iris following Accidental Perforating Wounds, with a Note on the Removal of Non-magnetic Foreign Bodies from the Anterior Chamber, which was considered to be helpful by the President and Sir William Lister.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A meeting of this section of the Royal Society of Medicine was held on March 5th, under the presidency of Mr. E. B. Waggett.

The Laryngostroboscope.

Dr. E. W. Scripture submitted a description of the laryngostroboscope. This consists of a disc with 40 slits mounted on the axle of an electric motor. The light from an arc lamp is concentrated by condenser lenses, so that it passes at a focus through the slits. The beam is caught by another lens, it falls on a flat head-mirror, and is reflected by the throat-mirror to a focus at the glottis. Dr. Scripture said he had observed that for the chest register the vibrations take place along the entire glottis: for the head register the cartilaginous glottis is closed and the vibrations take place along the muscular glottis only.

Frontal Sinus Cases.

The meeting discussed a number of frontal sinus cases, shown by Mr. Herbert Tilley, Mr. Lawson Whale, Dr. James Donelan, and Mr. Norman Patterson, the debate turning chiefly on the respective merits of the intranasal as compared with the extranasal route.—Dr. Dan McKenzie said his experience of the intranasal operation had been, to a considerable extent, successful; it was not very severe to the patient, and gave relief from the acute symptoms. But he had had one death following it on account of osteomyelitis.

The President pointed out that the success of the internal operation depended on the anatomy of the part, and hence a stereoscopic skiagram was essential before arriving at a decision concerning the route to be taken. He had not yet had osteomyelitis develop in a case, but, like others, he went in terror of it. At the outer angle, the dangerous part, there should be a drainage-tube, and it should be retained five or six days. In the absence of a good skiagram, he advocated the use of the Doyen perforator in the external operation, then if the dura were encountered, the operation was robbed of danger.—Mr. Cyril Horsford related two cases in which he had serious complications and the measures by which he successfully combated the danger.—Mr. J. F. O'Malley considered that both the external and the internal operations had their place in frontal sinus surgery, and the exercise of care would enable a decision to be made.

Radium in Malignant Disease.

Mr. Douglas Harmer and Dr. N. S. Finzi showed a series of patients whose malignant disease in various situations had been treated by radium. In one of sarcoma of tonsil the radium had caused the tumour almost to disappear. In one of endothelioma of pharynx radium brought about a great reduction in size, and after a somewhat severe surgical operation X rays were administered. In a case of mixed parotid type tumour of the palate the success from the radium was moderate. An endothelioma of the palate was caused by radium to shrink rapidly. A case of what appeared to be carcinoma of the orbit was not improved by the radium imbedded. The last was one of a large fibro-angeioma of the nasopharynx. There was rapid shrinking of the growth following radium application, but it was followed by extensive necrosis of the maxilla and perforation of the hard palate.

Mr. W. M. Mollison showed a patient with Lupus of the Palate. The Wassermann reaction was positive; no tubercle bacilli were found in the sputum.—Mr. Harmer said he had just cured in a month a similar case by the method of giving large doses of iodide of potassium and at the same time ionising the palate.

Other interesting cases were shown.

MEDICAL SOCIETY OF LONDON.

HEAT HYPERPYREXIA.

A MEETING of this society was held on March 8th, Mr. V. WARREN LOW, the President, being in the chair, when papers were read on Heat Hyperpyrexia.

Dr. W. H. WILLCOX spoke of the clinical aspect of the condition. An abstract of his paper appears in another part of our present issue.

Physiological Aspect of Heat-stroke.

Professor LEONARD HILL spoke from the physiological aspect. He said that heat-stroke was due to rise of body temperature to a height incompatible with life. The ultra-microscope showed the aggregation of particles in cell protoplasm increasing with the temperature. The heat-regulating mechanism might fail to control the body temperature under the atmospheric conditions or become exhausted. Sun-stroke was a form of heat-stroke, the absorption of the sun's energy by clothes or dry skin helping greatly to heat the body. The wet skin kept off sun-heat, this being dissipated by reflection and evaporation. The sun tempered by a cooling breeze burned the untanned skin, but could not cause sun-stroke. Men should become tanned so that they could wear thin cotton clothes open at neck, arm, and knee. Diet was of importance in the tropics, proteins with high heating power required to be reduced; temperance was essential, for alcohol, while supplying fuel value, could not supply the essential protein-building stores and vitamines. Monkeys fed on bananas and rice and given plenty of water could be trained to withstand exposure to the tropical sun. The sweating mechanism became developed with training.

Effect of enclosure by clothes and walls.—This, the speaker said, was very important. Air kept in contact with the body became warmed and saturated at skin temperature and heat loss became impossible. Rise of body temperature accelerated heat production, and a vicious circle resulted. The victims of the Black Hole died of heat-stroke. The body, weighing 70 kg., took some time to heat up, hence people withstood a hot bath or overcrowding in hot rooms for a time. Overheating the body increased the pulse-rate, lowered the systolic pressure, and lessened the power to compensate for the influence of gravity on the circulation. Those with circulatory defect or instability suffered first. Wind greatly increased the convective cooling power of air when the dry bulb was less than body temperature, and the convective warming power of air when the dry bulb was above body temperature. Wind greatly increased the evaporative cooling power of air so long as the dew-point was below body temperature. The kata-thermometer illustrated these facts. It was essential that a comfortable, cooling, and evaporative power should be secured in all workshops so as to prevent both over-cooling and heat-stagnation and increase efficiency, which was particularly lowered by the latter. To cite an example, with dry bulb at 89° and wet bulb at 73° F., conditions were intolerable in still air, comfortable in air moving at 1 metre per second. Suppose the air were saturated and the wet bulb were also 89° (not uncommon in Borneo), a wind of 9 metres per second (20 miles an hour) was required to give a comfortable cooling effect. Hence the enormous importance of fans and punkahs, of houses built in the tropics so as to keep off sun-heat and allow every breeze to blow through, of clothes thin, loose, and with wide openings for ventilation. Compressed air escaped cool and dry, and might be used as a cooling douche in conditions where wind did not suffice—e.g., in mines, where the wet bulb approximated to body temperature. Freezing appliances could be of little value for tropical houses; they were costly and unhealthy. A dry, hot wind, such as the simoon, might overcome the cooling power of the sweating mechanism. The wet skin reflected and evaporated off the sun-rays. The clothes and dry skin absorbed them, and black clothes much more than white. The pigment of the coloured races, by absorbing the sun-rays, prevented sunburn and activated the sweating mechanism. It allowed the skin to be thin and the blood-vessels superficial, so that those parts in the shade cooled readily. Heat-stroke was not an infectious disease; it could be produced in normal people under the exact conditions of the experimental chamber. It could be prevented by treatment based on the physical laws of cooling. The critical temperature demanding immediate relief seemed to be 107° to 108° F.

In moist still heat the cooling mechanism of the body failed in spite of being fully at work; as treatment a cooler environment must be secured. In dry heat the sweating mechanism became exhausted; a dry skin preceded and was the signal of impending heat-stroke. G. K. Hearne at Basra found that the patients with dry skin asked for the roof fans to be turned off. They were heated up just as the dry kata-thermometer was heated up by the wind, the temperature (dry bulb) being above body temperature. The sweating patients begged for the fans to be kept on; they were cooled as the wet kata-thermometer was cooled by the warm wind. After realising the danger of the dry skin he stopped all further cases of heat-stroke by water sprays and fans. The great point was to recognise the danger of the dry skin and to get the case under treatment before the temperature rose to a critical height. No other treatment but the spray and fan was required. Infection, constipation, fatigue, and drink, by weakening the heat-regulating mechanism, contributed to heat-stroke. Cramer had pointed out that both infection and exposure to a hot atmosphere caused hyper-action, followed by exhaustion, of the adrenals. Injection of tetrahydronaphthylamin produced pyrexia, with increased action of the adrenal glands, conversion of glycogen into sugar, &c. Cramer found that narcotics such as chloral counteracted this experimental heat-stroke. It was obvious that narcotics could not control heat-stroke in a man who had ceased to sweat and was in an atmosphere warmer than his body. The kata-thermometer indicated conditions of the atmosphere which were likely to cause heat-stroke. The surface temperature of a piece of black fur indicated the radiant energy of the sun.

Experiences in Mesopotamia.

Dr. A. FEILING spoke of his own experiences in Mesopotamia. He had been struck by the comparative rarity of heat hyperpyrexia in previously healthy men. He had seen a number of cases in a hospital for paratyphoid cases, of which he was in charge, and had found it advisable, if the temperature reached 103° F. or so, to cover the patients with sheets wrung out in cold water and to place them under an electric fan. If the heat regulating mechanism were disturbed heat hyperpyrexia might result even when the protection from the sun's rays was unusually complete. He also laid stress on the protracted nature of the convalescence in heat hyperpyrexia cases. Sweating was suppressed often for from 7 to 10 days and perhaps longer, and pyrexia recurred on the slightest provocation. Among the sequelæ was headache, very intractable in nature, perhaps lasting for many months. He had used the kata-thermometer and his investigations showed that free currents of air were essential in the prophylaxis. During 1917 and 1918 he had been greatly puzzled by a group of cases in which exhaustion, vomiting, and sometimes diarrhœa, were met with and in which the clinical picture was one of exhaustion and neurasthenia; possibly these were examples of adrenal exhaustion. He had obtained no success from venesection as a means of controlling the convulsions, and chloroform had sometimes been necessary. He had found it very difficult to produce sweating, though he regarded the suppression of sweat as a result and not the cause of heat hyperpyrexia.

Mr. CAMPBELL WILLIAMS asked concerning the after-results, and mentioned two patients who had become insane.

Blood Pressure a Factor in the Disease.

Mr. V. Z. COPE suggested that the greater prevalence among Europeans might be explained by the fact that they ate more meat. He regarded absence of sweating as a cause and not an effect. He had noticed that heat hyperpyrexia exaggerated the action of a small dose of anæsthetic and prolonged the anæsthesia in a case. In another case in which there were jactitations the movements ceased when a pint of blood had been removed by venesection, but began again when a pint of saline had been injected. This suggested that blood pressure was a factor to be considered. Pointing in the same direction was another clinical experience. Two pints of saline were injected into a patient with subnormal temperature and prostration: this led to improvement, but hyperpyrexia then ensued.

Sir **WILLIAM HALE WHITE** regarded heat hyperpyrexia as due to a breaking down of the heat-regulating mechanism. The symptoms produced by tetra-hydronaphthylamin were distinct from those of heat-stroke. The greatest number of cases met with under peace conditions occurred in people with some affection of the nervous system.

Difficulties in Diagnosis.

Dr. P. **MANSON-BAHR** said that in Egypt he had met with only a few cases: they coincided with the prevalence of a hot wind. He laid stress on the importance and difficulty of the diagnosis from malignant malaria, with which heat hyperpyrexia had been often confused in West Africa. This was added to by the paucity of organisms in the peripheral blood in the first 36 hours of an attack of malignant malaria. Many patients harboured the parasites, but were without symptoms until the incidence of a heat wave, when cerebral malaria occurred. The microscopic evidence was, therefore, often deceptive in the early stages, nor was splenic enlargement very helpful. The distinction was important, for if cases of malignant malaria were treated as heat hyperpyrexia fatal collapse was prone to occur.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

CHRONIC HALLUCINATORY PSYCHOSIS.

THE ordinary quarterly meeting of this association was held at 11, Chandos-street, London, W., on Feb. 24th, under the presidency of Dr. **BEDFORD PIERCE**.

Dr. R. **HUNTER STEEN**, medical superintendent, City of London Mental Hospital, read a paper on Chronic Hallucinatory Psychosis. The contribution was founded upon a series of cases in which the principal symptom was the presence of hallucinations. As the hallucinations cause slight depression, some of the cases might be included under melancholia, while the development of delusions of persecution might lead to a provisional diagnosis of paranoia being made. Others, again, might be swept into the wide net of dementia præcox—an unsatisfactory state of affairs. He set out to show that there are hallucinatory cases which can be grouped together into a well-defined clinical entity, for which he proposed the term chronic hallucinatory psychosis. The most prominent of the hallucinations are the auditory. The patient may, for years, recognise that his hallucinations are morbid and unaccountable. These patients cannot at first be termed insane, hence Dr. Steen preferred the word "psychosis" to "insanity." In the absence of an explanation the patient tries to account for their presence, and there then results a delusion, mostly one of persecution. In the early stages such a patient is quiet and orderly, and the memory is good. The speaker quoted several typical cases, some of them from French literature. In one of Dr. Steen's cases, after the revelation to him of the subject of a severe mental conflict, there was marked improvement for three years, although at the end of that time the patient returned with the symptoms more persistent than ever. One patient definitely heard various animals talking to her and had symptoms of dissociation. In most of the cases—for it could not be regarded as a rare affection—careful research into the family history would reveal a strong hereditary tendency to nervous instability.

It seemed to be an affection of adult life, beginning between 30 and 50 years of age usually. It was met with mostly in women, and not those of the lowest rank of life. Some observers suggested that an illness like pneumonia might act as a predisposing cause, but that had not been Dr. Steen's experience. A history of physical injury might be met with. There was no known special morbid anatomy of the condition. Not one of his cases had died, and he did not know of any other observers having published accounts of post-mortem examinations in such cases. The phenomena could be best understood if approached from the psychical side purely, though several theories had been advanced founded upon material conceptions. Hallucination was the result of dissociation of the mind, directly produced by a mental conflict which had been sternly repressed, perhaps for a long time, in a person congenitally unstable mentally. Sleeplessness was not a prominent symptom except in the later stages of the disorder. In a late stage the expression became anxious, a listening attitude may be noted, and the voices may be conversed with. Violence may be threatened and suicide suggested. Though there are periods of remission, on the whole the disease steadily progresses in intensity, and, having reached its zenith, remains stationary for several years.

Differential Diagnosis.

Dr. Steen discussed the differential diagnosis of the condition from general paralysis of the insane, the manic-depressive group, true melancholia, the secondary and organic dementias, and paranoia, the last-named being the most difficult in the matter of differentiation. With regard to prognosis, the earlier a case is seen the more hopeful is the outlook. When delusions have developed but little can be done to avert chronicity. The general health is not affected, and there appears to be no danger of terminal dementia. In the early stages benefit is sometimes derived from a change of environment. Rest from work, freedom from anxiety, and change of air and scene should be advised, while plenty of nourishing food should be taken and the bowels kept regular. In some cases it is well to give an occasional hypnotic to secure sleep. If, however, small doses of the bromides or hydrobromic acid do not lead to improvement, a thorough mental examination must be made; it will probably bring to light a mental conflict which has caused the dissociation. The present difficulty of getting into touch with these cases in the early stage is likely to be less in the future, with the multiplication of mental out-patient departments attached to large hospitals.

Discussion.

The **PRESIDENT** did not consider that Dr. Steen had quite established the claim to regard the malady he described as a separate disease from paranoia. Paranoia was shown by Dr. Percy Smith, in his presidential address, to be an exact clinical entity. He (the speaker) asked how it was possible for a mental conflict to produce dissociation.

Dr. W. F. **MENZIES** said that this type of case became very demented in the course of 20 or 25 years, resulting in the patients becoming chronic lunatics. Post mortem, there was always found to be more or less thickening and chronic resolution. The cases were first called paranoia, and then chronic maniacs. These matters were not, he thought, to be regarded purely from the psychical standpoint; he believed that unless the anatomical, and especially the chemical aspects were also considered, there would not be much advance.

Dr. **PERCY SMITH** said observers in various countries who described paranoia had referred to acute hallucinatory paranoia and chronic hallucinatory paranoia: and included in the writings upon paranoia were almost all kinds of acute psychosis met with—even acute delirious conditions, which was absurd. It would be too sweeping to assert that in no cases of paranoia were there hallucinations. In the address which had been referred to he had pointed out that chronic hallucinatory cases, to which the term paranoia was properly applied, often began with a serious emotional disturbance. Many cases of paranoia had hallucinations. He thought it likely that psycho-analysis would help in the early stages of the cases described by Dr. Steen.

Dr. STEEN, in reply, said he was not prepared with an explanation as to how a mental conflict produced dissociation, but he entertained no doubt as to the fact, especially when the conflict was strongly repressed. He pointed to the case in his paper in which the revelation of this source of conflict was followed by relief for three years. He agreed there were hallucinations in some cases of paranoia, but paranoia was a disease characterised by delusions, with, as a rule, absence of hallucinations: certainly the latter were not characteristic of paranoia, while they were of the cases now described. In a review of the cases, the assumption of a causal physical basis had not afforded him any help, but an approach from the psychical side gave him a better insight into the condition. Early psycho-analysis, he believed, would enable many cases to recover.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE DIAGNOSIS OF GONORRHŒA: A STUDY OF 500 CASES.

A MEETING of this society was held at Liverpool on Feb. 20th, with Mr. MILES H. PHILLIPS, the President, in the chair, when Dr. W. W. KING (Sheffield) read a paper on the Diagnosis of Gonorrhœa, based upon an analysis of the first 500 cases under his care at the venereal clinic of the Jessop Hospital for Women, Sheffield. He divided the cases into two groups—those in which the gonococcus had been found ("proved" gonorrhœa), and those presenting the signs and symptoms of the disease, but where the specific organism had not been isolated ("clinical" gonorrhœa). The gonococcus was found in 60 per cent. of cases presenting clinical symptoms of gonorrhœa, but in a number of these was only isolated after repeated examinations. He estimated that from 70 to 80 per cent. of patients with the physical signs mentioned later were really suffering from gonorrhœa. Of the remaining 30 per cent. the majority were venereal, but in one case the infection appeared to be due to a diphtheroid bacillus present in the cervical and urethral discharge.

The symptoms complained of were discharge (yellow or white), pain on micturition, local pain and swelling, abdominal pain, menorrhagia, and irritation. Yellow discharge was present in over 70 per cent., and pain on micturition in about 30 per cent. of both "proved" and "clinical" cases. The physical signs noted were vaginal discharge, vulvitis, papillomata, leucoplakia, lesions of Bartholin's gland, urethral discharge or thickening, urethral caruncles, vaginitis, and affections of the cervix uteri. Vaginal discharge was present in 80 to 90 per cent. of all cases. Acute gonococcal vulvitis was not often met with, most of the cases seen at the clinic being in the subacute or chronic stages. In about 80 per cent. of cases there was a purulent urethral discharge, but in a small number the discharge was white in colour and composed of epithelial cells in which the gonococcus was sometimes found. Thickening of the urethra was most valuable evidence of past gonorrhœa in the female, and was comparable in this respect to stricture in the male. Infection of Bartholin's gland was only met with in 10 per cent. of cases.

The commonest evidence of cervical infection was purulent or muco-purulent discharge usually associated with a patulous condition of the external os. The combination of purulent discharge and patulous cervix was a helpful diagnostic sign, especially if the internal os was also sufficiently patent to admit a "dressed" probe into the uterine cavity. In more chronic cases the discharge consisted of a clear mucus, and this, coming through a patulous external os, produced a bull's-eye lantern effect which he had called a "magnifying" cervix. The magnifying cervix was typically seen in nulliparæ, but occurred also, though less strikingly, in women who had borne children. This condition corresponded to the gleet stage of gonorrhœa in the male, and occurred in about 15 per cent. of cases. The inguinal glands were rarely found enlarged in uncomplicated gonorrhœa. When enlargement was present he always suspected the presence of syphilis. Salpingitis was the most frequent complication of gonorrhœa met with (18 per cent. "proved" cases, 12 per cent. "clinical" cases). No case of gonococcal cystitis was noted in the series, although generally stated to be of fairly frequent occurrence.

Detection of the gonococcus in film preparation was at present the only certain method of diagnosis. The method of preparation of these films was important. "Dressed" wires were used for collecting the material which was dabbed—not rubbed—on to the slides. In this way, the leucocytes were preserved intact and the intracellular features of the gonococcus more easily observed. The importance of the urethra in the bacteriological diagnosis was shown by the fact that the organism, when found, was present in the urethral discharge in over 70 per cent. of cases. If found at all, the gonococcus was generally detected in the first five examinations, but in some cases not until the eleventh or twelfth. Cultural methods were extremely difficult to carry out with the highly contaminated pus present in the female. We must look, therefore, to some serum reaction which will put the diagnosis of the disease on a surer footing than at present. The technique of the complement-fixation test for gonorrhœa is at present imperfect.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society, held on March 4th, Professor J. B. Leathes read a paper on the Function of the Kidney in Nephritis. He began by referring to results described to the Association of Physicians in July last,[1] showing that two common failures in the cases of war nephritis examined were loss of diuretic response to the intake of water and absence of the matutinal alkaline tide, two independent phenomena, either of which occurred without the other. The persistence of the nocturnal urinary acidity throughout the first hours after waking showed that it was not to inability of the kidney to remove acid that a tendency to dyspnœa in such cases should be traced. The normal acidity of the urine in the evening and at night is normally accompanied by a considerable increase in the output of phosphate, and the fact that a diuresis induced by phosphate, unlike that produced by other agents, is an acid diuresis, suggested that the amount of phosphate excreted by subjects who exhibited no alkaline tide might be found to be high. But this was not the case; nor was the phosphate increased, as chloride and nitrogen output are, by the diuretic flood. Taking average figures from more than 100 tests, with the hourly output of water increased to four times as much as it was during the night, the hourly output of phosphate fell at the same time to two-thirds of what it had been before the diuresis, a proportion observed equally when there was and when there was no alkaline tide. Cushny has shown that a partial obstruction to one ureter, hindering the escape of urine, tends to diminish the volume and increase the acidity of the urine from that kidney [illegible] compared with the other. Obstruction in the tubules, due to the presence of red blood corpuscles or blood clots, conceivably might account for diminished volume with increased acidity in some of these cases; and it was observed that it was particularly in cases that persistently passed granular casts (which can be shown to contain altered blood pigment and from which hæmatin can be prepared) that this combination of small volume and high acidity was common. Another peculiarity found in cases of nephritis, the tendency for the retention of chlorides rather than of urea, might also be accounted for by films of blood clot on filtering surfaces, if it were shown that clotted blood exhibited the properties in regard to permeability which characterise red blood corpuscles—namely, permeability to urea but not to sodium chloride. Experiments with blood clotted in thin layers on dialyser membranes have been begun, and so far have shown a remarkable impermeability of the clot to sodium chloride. Whether this may account for the phenomenon common in these cases of nephritis the experiments are not yet sufficient to decide. The very great majority were clearly cases of acute glomerulitis in which hæmorrhage from glomerular tufts [illegible] probably one of the earliest disturbances, and in some degree is probably constant.—Professor A. J. Hall, Dr. A. E. Barnes, Dr. A. E. Naish, Dr. R. G. Abercrombie, among others, took part in the further discussion.

Reviews and Notices of Books.

PRACTICAL PHARMACOLOGY.

For the Use of Students of Medicine. By W. E. DIXON, M.D., F.R.S. London: Cambridge University Press. 1920. Pp. 90. 7*s.* 6*d.*

THE old materia medica is passing away, with its study of barks and roots and seeds and the preparation of mysterious compounds by bored and unwilling students. In its place has arisen the newer study of the action of the drugs in man and animals with more or less successful attempts to explain the way in which they affect disease. In most schools this discipline precedes attendance in the wards or, at the latest, is taken in the beginning of the clinical work, when the student is still unfamiliar with the aspect of disease and can hardly be expected to follow very closely the changes wrought by treatment. This position in the curriculum, necessitated by the close dependence of pharmacology on physiology, results in a certain want of reality in the treatment of the subject, and in order to remove this a number of books on practical pharmacology have been issued of late years, chiefly in the United States. In some of these the student seems to be expected to spend his time, which must apparently extend over months, in performing experiments on animals, which would be formidable operations for a trained physiologist, and in which one would suppose that the chief interest must lie in the preparatory operation rather than in the drug action which it is expected to illustrate.

Professor Dixon's little book avoids this spectacular method and deals largely with such facts as can be demonstrated in simpler ways, with test-tubes and frog muscles and hearts, and in that way seems admirably adapted to give the student some insight into the way in which drugs affect living tissues. It begins with the action of drugs on proteins, ferments, and protozoa, and proceeds in succeeding chapters through experiments on striped and plain muscle and blood to those on the heart and blood-vessels, glands, and central nervous system. The excretion of drugs is treated of, and some experiments to be done on the students themselves are suggested. We hope that this chapter may be expanded in future issues. Nothing interests the student more, and nothing can be more useful than the examination of his fellows for symptoms, especially if he is not informed beforehand what drug has been given. The final chapter on the physical (it used to be the "sensible") properties of drugs would shock the old teachers of materia medica by its brevity, but is on the right lines.

While we are not prepared to endorse all the statements made by Professor Dixon, we can cordially commend this book to the attention of teachers. Even if they differ from the author in many points, they will find—what many are seeking—a type of practical work to give their students as a substitute for the old practical materia medica, of which they have begun to doubt the utility.

GUNSHOT WOUNDS.

Contribution à l'Étude du Traitement de Plaies de Guerre par la Méthode Mencière. By Dr. FRANCIS BRABANDER, Médecin Aide-Major de 2^{e} classe. Paris: Ollier-Henry. 1920. Pp. 142.

THIS is a monograph describing Dr. Louis Mencière's method of treating gunshot wounds. The method consists of introducing into the wound a mixture of iodoform, guaiacol, eucalyptol, balsam of Peru, alcohol, and ether. It is claimed that with its use excellent results were obtained—and no doubt they were an accompaniment. It is noted, though, that before using the mixture the wound should be excised and all foreign bodies removed. Most surgeons agree now that the ideal treatment of war wounds is early excision and early suture, and that the additional employment of any of the innumerable antiseptics which have been vaunted is of the minimal importance.

THE HEALTH OFFICER.

By F. OVERTON and W. J. DENNO. London and Philadelphia: W. B. Saunders Company. 1919. Pp. 512. 20*s.*

THE Ministry of Health has many problems before it and among them not least in importance is the position of the medical officer of health. Is he to remain a servant of the local authority, or is he to become a State official? Is he to devote his time entirely to hygiene, sanitation, and the preventive side of medicine, or is he to be brought into closer touch with the general practitioner and the curative side? Questions such as these cannot be determined without careful thought, and advantage is gained by learning what is the position of health officers in other countries than our own. Already we have learnt much from America—as, for instance, from Alex. Flexner in relation to medical education—and we can obtain further valuable light upon the possibilities which lie within the duties of a health officer by considering how this office is worked in the States.

A useful book for this purpose has just been published, and we gather therefrom that in the States the health officer steers a middle course between local and State supervision. "A health officer derives part of his authority from the State laws and part from local ordinances. When he acts under a State law he has the prestige and power of the State to support him. But when he acts under a local ordinance he is not always sure of the support of the local board of health. If he has the active coöperation of his board of health he may be reasonably sure that he has sufficient power to carry out his work. If the board is lukewarm or hostile, he can do little under the local ordinances." Legislation in the States would appear to be on somewhat different lines from those followed here. First, there are certain statute laws which lay down the broad principles of hygiene. Each State, however, has its own laws. Then come sanitary codes, which lay down in detail the way in which these principles shall be administered. These codes only apply to definite districts and areas which adopt them, but once adopted they have full legal power. "The universal intent is that the State Department of Health shall assume command when actual danger is at hand, and at other times shall act as a kindly teacher and counsellor to the local health authorities. For example, a state department of health will examine a public water-supply, and if the water is not pure, it will point out the sources of pollution and will advise the local authorities regarding remedial measures; but if the pollution produces sickness, the State Department of Health may take charge of the situation and compel the local authorities to remedy the conditions."

Beyond these ordinances the health officer seems to have a wide discretion, thus, "public sentiment and the courts grant almost dictatorial powers of the health officer in the presence of an epidemic," and as long as his actions can be held to follow within the broad principles of the statute law, he would appear to be able to act on wider lines than those to which the sanitary codes of his district might be held to restrict him. In the States as well as here development in the outlook on medicine appears to be progressive, and "the health officer is expected to improve social conditions which foster physical defects and sickness. He is also a physician to the strong and the well, and seeks to maintain a high standard of health and efficiency in a community. The next great development in medical practice will be the treatment of the well, and in this movement the leaders will be the health officers." More often than in this country the health officer appears to be a general practitioner practising in the area for the general health of which he is responsible; and the possibility of drawing closer the preventive and curative side of practice seems to be easier.

The authors of this book hold that even to-day a practitioner has double duties. "Those who employ a physician have a right to expect that he will advise them not only how they may recover from sickness, but also how they may prevent the sickness from developing again in the future, and from spreading the disease to other persons. The laws and sanitary code of New York State recognise these obligations, and require physicians to perform specific duties which make them an official part of the public health organisation of the State."

They also point out how, as in this country, public health is developing steadily on individualistic lines as distinct from communistic. A claim is made that from a widespread campaign of personal education great results can be obtained, in support of which the health record of New York city is quoted. Whether this is a case of *post hoc ergo propter hoc* or not, the record is certainly astonishing, for we learn that the death-rate in the city became in 1910 as low as that of the surrounding rural districts, and has been below that in rural districts ever since, so that "the country no longer needs health protection against the city, but the city must be protected against the unhealthful influences of the rural districts. The public health problem of the future is to bring the work of the country up to the standard of that in the city."

Apart, however, from its wider interest to us at the present time, this book is an exceedingly useful volume. The authors seem to have adopted the sound principle of taking for granted that their readers know nothing. They therefore start from the beginning and in simple words tell their story. Nevertheless, they carry the story forward to include the most recent knowledge on each of the subjects treated. We strongly recommend those who are making the acquaintance of preventive medicine to obtain this book. It is as useful here as in the States, and the American way of emphasising and drawing attention to detail and fact cannot fail to be of use and to interest medical officers of health and sanitarians of all kinds.

ATLAS OF PLASTIC SURGERY.

A Stereoscopic Atlas of Plastic Surgery of the Face, Head, and Neck, by JOSEPH C. BECK and IZA FRANK, Chicago. London: Henry Kimpton. 1920. 35*s.* net (with stereoscope).

THIS Atlas includes a series of stereoscopic plates, designed to summarise the more common operations met with in plastic head surgery. In addition to the pictures, there are added brief case-reports.

JOURNALS.

Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LIII., No. 5. 1920. Cambridge University Press. Pp. 273–366. 7*s.* 6*d.*—On Physiological Radio-Activity, by H. Zwaardemaker. No representative of the heavy radio-active elements belonging to the three groups—radium, thorium, and actinium—is found in the animal organism, except, perhaps, a trace of emanation, but potassium to the amount of 40 gr.—one of the light radio-active elements —occurs as a permanent constituent of the body. It is stored for a great part in the muscle cells and red blood corpuscles, and rather more than 1 gr. in the blood as a free diffusible ion. The potassium ion is known to be indispensable to cardiac action, and it appears to be its radio-activity which is answerable for this action. Perfusing a frog's heart through a Kronecker cannula it was found that a radio-active element, whatsoever it may be, added, in a dosage of equivalent radio-activity, to a potassium-free Ringer's mixture, renders such a solution as effectual a circulatory fluid for the heart of a cold-blooded animal as the original fluid; strong hearts may continue beating for hours. No inactive radio element was found that could replace potassium in Ringer's mixture; α-emitting bodies taken up in potassium-free Ringer's solution proved excellent potassium substitutes. There is also an antagonism between light and heavy radio-active atoms not only for the frog's heart, but also for other systems—e.g., vascular endothelium. Perfusion of oxygenated Ringer's fluid through a newly killed water frog even for 24 hours is not followed by œdema, but if potassium is omitted from the perfused fluid a violent œdema is developed. This œdema can be prevented by replacing potassium by its substitutes (Rb, U, Th). It is known that the glomerulus-epithelium of the frog's kidney completely checks glucose in Ringer's fluid from appearing in the urine, and that glucose appears in the urine directly the potassium is left out. Instead of potassium uranium or radium may be taken in such dosage as is required to prevent œdema. Emanation—a chemically indifferent gas, Ramsay's niton—emits α-rays. This emanation, added to a potassium-free Ringer's solution, will restore the beat of a heart brought to a standstill through removal of the potassium. "It is certain that radio-activity is a mighty biological factor, capable of restoring a lost function. Such a factor may act either as a cause or as a condition." It is concluded that in a large number of systems—heart muscle, vascular and glomerular epithelium—the potassium atom may be replaced by other radio-active elements, the heavy ones as well as the light ones, provided the dosages are of equal radio-activity. When applied simultaneously the substances emitting α-rays and those emitting β-rays are reciprocally antagonistic. Potassium is (as bearer of the physiological radio-activity) for many cells a stimulus, which can restore and sustain function when it is brought in contact with the surface of cells, as a free, diffusible ion in the circulating fluid. A free radio-active substance can take the place of potassium when previously the potassium is omitted from the circulation.—Studies in the Regeneration of Denervated Mammalian Muscle: III. Effects of Massage and Electrical Treatment. By F. A. Hartman and S.-Sgt. W. E. Blatz. Neither massage nor galvanic stimulation appeared to benefit denervated muscle.—The Relation of the Animal Cell to Electrolytes. I. A Physiological Study of the Egg of the Trout, by J. Gray, M.A. The author describes the normal fertilisation of the egg of the trout—laid during the winter months from November until March—as well as the artificial "dry" method of fertilisation. The latter method yields 90 per cent. of fertilised eggs, the former perhaps only 8–10 per cent. In the "dry" method the sperm and eggs are mixed together and water is then added, so that each egg is surrounded by highly motile spermatozoa and fertilisation is assured, and it would appear that the actual entrance of the sperm nucleus into the egg takes place within half a minute after mixing the egg with sperm. The spermatozoa in the spermatic fluid are quite motionless, but if a very small drop of sperm is placed in the centre of a drop of water and examined under the microscope the spermatozoa near the junction of the two drops are seen to be intensely active. The spermatozoa are only motile when they come in contact with water, and the period of motility is extremely short—1½–2½ minutes. Hence the reason why the "dry" method is so much more effective than the "wet" or normal method, where the male sheds its sperm directly into the water over the position of the eggs, and few spermatozoa remain long enough motile to reach the eggs. Both fertilised and non-fertilised eggs contain a considerable amount of electrolytes. When an egg is injured or dies rapid exosmosis of electrolytes takes place. The egg never becomes permeable to intracellular colloids. After fertilisation electrolytes do not appear to diffuse out of normal eggs. The freezing point of the egg-contents is approximately that of the blood of fresh-water teleosts. The whole of the intracellular electrolytes can be removed by a dialysis of the cell contents, while the proteins within the cell—largely consisting of globulins, held in solution during life by neutral salts—are precipitated. This also occurs when the egg dies. The whole of the obvious changes produced in the dead egg are explicable by a study of the properties of the intracellular globulins—e.g., the change in size produced by acids and alkalies. The controlling factor of the high electrolytic content of the living cell appears to be located in the thin protoplasmic membrane lining the egg shell.—Other papers in this number are: The Time Relations of the Blood-Pressure Changes after Excision of the Adrenal Glands, with some Observations on Blood Volume Changes, by H. C. Bazett.—The Reaction and Carbon-Dioxide Carrying Power of the Blood: A Mathematical

Treatment, Part II., by T. R. Parsons.—The Influence of the State of the Blood on the Interworking of the Eyes, by Walter M. Coleman.

Veterinary Review. Edited by O. CHARNOCK BRADLEY, M.D., D.Sc., M.R.C.V.S. Vol. IV., No. 1. February, 1920. Issued quarterly. Price 6*s.*; annual subscription, 16*s.* 6*d.* Edinburgh: W. Green and Son, Ltd.—This number contains an opening article on the importance and value of an accurate veterinary bibliography. The writer, Mr. F. Bullock, secretary of the R.C.V.S., criticises bibliographies as frequently given by authors of literary and scientific articles and books. He points out many of the errors and omissions made in numerous examples taken from recent literature, and gives instructions as to how correct bibliographies should be compiled. Latitude should be given to the inspiration aroused by the perusal of other men's works, and personal attributes and phases of thought cannot be docketed as strict bibliographical references. The contents of the *Review* are divided into five main sections, comprising abstracts, reports, reviews, notes on books, and bibliography. All the section are carefully written and compiled, and although only a young periodical, the *Review* is quite justifying its existence as a big mine of useful information. The divisions on reviews and notes on books are very valuable, as they keep readers abreast of current literature, and indicate that veterinary thought and research, taken as a whole, is alive and alert.

Le Scalpel. Bulletin de la Fédération Médicale Belge, 47, rue Dautzenberg, Brussels. 20 francs per annum. Vol. LXXIII. Nos. 3-6.—The problems of venereal disease are as much in the minds of our continental colleagues as in our own. In Belgium an article on the "péril vénérien," which appeared in *Le Scalpel* for Nov. 16th last has served as a touchstone to light the fires of controversy, and three out of the four numbers under review devote space to the subject.

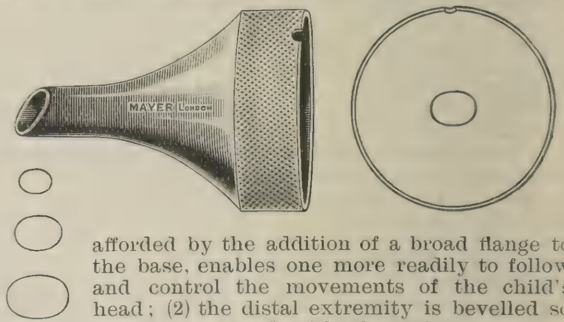
Dr. Bayet, of Brussels, contributes a paper, read in the first place before the Belgian Academy of Medicine, which deals critically and forcibly with the whole problem of venereal prophylaxis. After reviewing the various causes which have contributed to the great increase of venereal disease in Belgium—the German occupation, the laxity of morals associated with war, the demobilisation of their own army—Dr. Bayet turns in castigation upon the measures adopted to combat this plague. For "regulated prostitution" he has no good word to say. After 130 years this method is proved useless by the fact that the evil against which it was invoked was almost as rampant even before the war as on the day when State control was first enforced. The causes of immorality are deeply rooted in social conditions, and only the abolition of poverty which makes early marriage impossible will do away with illicit intercourse. But to-day the disease exists, and to fight it we must attack the germs in the bodies of those who convey it. This is the true basis of prophylaxis. All infected persons must be treated, and whether or not they are cured of the disease, at least we must be sure that they are rendered incapable of infecting others. To this end every encouragement to seek aid must be given to those who have taken the disease. Centres must be constituted where gratuitous treatment is afforded with due discretion. The State control of prostitutes makes this impossible, for so long as the policeman stands behind the doctor no woman will dare to apply at the clinics. Administrative prophylaxis has failed, and medical prophylaxis will only succeed if the whole profession unite in a broad-minded campaign to make it successful. The Ministry of the Interior (Department of Health and Hygiene) make the official position clear in *Le Scalpel* for Jan. 31st and Feb. 7th. They do not consider police supervision of prostitutes incompatible with medical treatment of the syphilitic population, since both are included in their plan of campaign. Apart from the first item, this resembles very closely the policy of our own Ministry of Health. Considerable stress is laid upon the value of education.

Other interesting articles include a research by Professor Laguesse (Lille) into the variability of the endocrine function of the pancreas, and a description by Dr. L. Ledoux (Brussels) of eight cases of severe stricture of the œsophagus resulting from burns. —Dr. Paul Denis claims to have succeeded in producing immunity as tested by the Widal reaction through the administration of a mixed vaccine (*B. typhosus*, *B. paratyphosus*, and *B. coli*) by the gastric route.—The abstracts appear to be selected from the French and Belgian medical press only, and book reviews are not numerous. Also, we must confess that the system of numbering the folios is a little bewildering.

New Inventions.

AN IMPROVED EAR SPECULUM.

THE difficulty of otoscopic examination in children has led me to devise an instrument (see figure) which, I believe, possesses some advantages over specula of the ordinary pattern. These are: (1) the good grip, afforded by the addition of a broad flange to the base, enables one more readily to follow and control the movements of the child's head; (2) the distal extremity is bevelled so as to correspond with the obliquity of the tympanic membrane when in position—the notch in the margin of the speculum should point upwards and backwards; (3) the instrument does not taper to a point, the terminal 10 mm. forming a tube of uniform calibre; (4) this tube is oval on cross section, but, owing to the bevelling, the distal opening is circular; (5) the plating is polished outside but dull within, and the speculum is made in three sizes, having terminal apertures of 3 mm., 4½ mm., and 6 mm., the larger sizes being suitable for adult use.

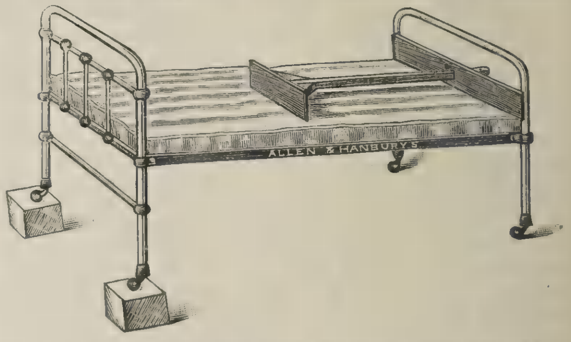


The makers are Messrs. Mayer and Phelps.

Edinburgh. DOUGLAS GUTHRIE, M.D., F.R.C.S.

A PROP FOR RETAINING PATIENTS IN THE FOWLER POSITION.

THE prop shown in the illustration has been devised for retaining patients in the Fowler position, and is easily adjusted and slipped down so that attention may be given to the pelvis when necessary. It is simple to clean and inexpensive. The head and shoulders well raised, the patient rests with the buttocks on a narrow shelf, on which is placed a small pillow, and a pillow is placed on each side of the vertical bar so that each leg may be supported. The peg is placed in a hole in the vertical bar at the foot of the bed, according to the length of the patient.



Messrs. Allen and Hanburys are the manufacturers.

Gloucester. C. FIRMIN CUTHBERT, F.R.C.S.

THE LANCET.

LONDON: SATURDAY, MARCH 20, 1920.

Robert Morant, Public Servant.

Robert Morant, First Secretary of the Ministry of Health, servant of the public in many great capacities, was at the centre of some of the most important developments of our society, and by his death the nation, and not only the medical profession, has lost an incomparable adviser. The widespread sorrow which has been caused by his sudden end last week has received a large measure of acknowledgment in the detailed records of his life which have appeared on all sides, so that we need not recapitulate in this place how the Wykehamist and Oxonian went rapidly from theology to schoolmastering, and then by dramatic transition to a confidential post at Siam, to welfare work in the East of London, and so to the Board of Education. Intensive study in the slums made him familiar with the social and educational defaults under which a large majority of the population of the country were dwelling, and his splendid work at the Education Office, culminating in his appointment as Permanent Secretary of the Board of Education, was made possible by his ripe experience, his sympathy with the unmerited drawbacks of those who get no chance, and above all by his large views of justice.

All this is interesting, because it is explanatory of the position and actions of the man who bore the brunt of many controversies over the National Insurance Act, and, it may be added, who never concealed his dislike of much that became the necessary procedure of that measure, even while the objectives of the vast piece of legislation were the expression of his own ideals. It was characteristic of Morant that, when he realised that the National Insurance Act was going to take the shape that it did, he suppressed all spirit of criticism in himself in order to extract from the new legislation the greatest good for the people. The working of the National Insurance Act, so far as its principal intention was the provision of medical assistance upon the insurance plan for a large section of the population, was hampered from the start by the want of preliminary preparation. The ground had never been properly surveyed before occupation, and muddles and altercations that might have been avoided marred the start of a measure which, upon its introduction, had received a unanimous ovation. To Morant there fell a large share of the constructive work which had to be undertaken in these unpromising circumstances, and his efforts were soon realised by the medical profession as being in accordance with a courageous desire to do right. But the working of the Act had hardly got into swing before the war broke out, with the result that a large proportion of the insured, and, relatively speaking, an even larger proportion of the medical men in charge of the health of the insured, were removed to new spheres of activity; of the doctors many of those in panel practice joined the colours, and those who remained behind had to discharge their duties in circumstances not comparable with any that were contemplated by the Act. Morant helped to enable the medical profession to meet the extreme claim upon them, and those who attended the sessions of the Central Medical War Committee will remember how hard he fought for the interests of medical men of all classes, as he regarded those interests, and how resolute he was that the maintenance of the health of the country and of the workers at home should count as second only in importance to the necessity of supplying the fighting men with adequate medical assistance.

During all the time between the passage of the National Insurance Act and the cessation of hostilities in the war Morant steadily grew in the esteem of the medical profession, who realised that in him they had a genuine friend, candid in respect of their weaknesses, but more clear-eyed than many of their own leaders in respect of their great qualities and potentialities; and when the Ministry of Health arrived he was unanimously marked out for his post. This was, moreover, as it should have been, for while the idea of such a Ministry had been present to the minds of medical reformers for at least three generations, it was Morant's idealism, broad range of experience, and powers of intimate concentration which counted incalculably in the transformation of the idea into a working organisation. He has died on a winning field, with the pathos that surrounds such a tragedy.

The Lessons of Statistical Methods.

A letter from Dr. H. E. Littledale appealed in The Lancet of Feb. 28th for the more extended use of statistics in their application to medical treatment; and in the same issue, dealing with the petition of the Royal Statistical Society for a State committee of inquiry into the collection and presentation of public statistics, we commented upon the use of figures in medicine. It is enticing to think that by an appeal to statistics we can settle once and for ever the best, the most successful, process of dealing with a pathological condition, but the dangers of accepting figures in their wrong significance are greater than neglecting their lessons entirely. In political matters it was long ago recognised that statistics could be made to support the most diverse ideas, and those who are watching the alcohol controversy will see that figures can be advanced purporting to prove on the one hand that alcohol is the main cause of poverty, and on the other that in countries where alcohol is used there is less poverty than in those which, in the picturesque language of America, are "dry." Statistics may be of immense value, but they must be used with the greatest caution, for their fallacies are apt to be concealed even from experts. Sound statistics, sifted and garnered in a right way, will form a firm foundation for trustworthy conclusions, and by statistics alone can a true idea of the value of some forms of treatment be based. But recognition of the limitations is necessary. An instance may be found in the serum treatment of tetanus. The prognosis of a case of tetanus is always doubtful; sometimes the most severe cases seem to recover when it is impossible to say that the treatment has saved them. Still more difficult is it to say, by the observation of isolated cases, whether the serum can prevent tetanus for many wounds that might be expected to be followed by tetanus never give rise to it, and even very slight wounds may end in an attack. It was only by the consideration of a long series of cases, in which every case of wound was treated with doses of the serum, that we could be certain that the serum had a definite and a very great power to prevent the development of the disease. Apart from the individualities of the patient and the uncertainties of diagnosis, we have to consider, when estimating the comparative value of any therapeutical procedure, all the environmental conditions, the stage of the disease, and perhaps the strain of a particular germ. These difficulties can only be met by observations so vast in number as to indicate the magnitude of the ideal.

Dr. LITTLEDALE'S suggestive letter may be referred to as showing alike how the need for statistical methods is felt, and how the scope of such methods is not fully recognised. By statistical methods we mean methods specially adapted to the elucidation of quantitative (numerical) data affected by a multiplicity of causes. Dr. LITTLEDALE asks for the results of 5000 operations of breast cancer as to duration of life, freedom from pain, and so forth; he also asks for the results in 5000 cases of breast cancer treated by any one or other method. It is not feasible to obtain the required data in any shape that can be called statistical. Pain, for instance, cannot be subjected to quantitative measurement, and it is extraordinarily difficult to determine its real seat of origin. If we consider the question of duration of life—a more obvious one for the application of statistical methods—we still find that we have no really simple task before us. It is said that the expectation of life in those on whom no operation has been performed is about 22 months, while in those who undergo a radical removal of the breast the expectation of life is 38 months. But this is not an answer to Dr. LITTLEDALE'S question. Suppose that careful notes have been taken of 5000 operation cases by two or three good surgeons whose percentage of so-called successes in early breast cases is approximately the same; and that 4000 sets of notes can be obtained of cases which have been only subjected to one special non-operative treatment by a few practitioners whose results are approximately equal—we depart purposely from Dr. LITTLEDALE'S figure to show that there is no point in identical numbers—it might be thought that the two sets of notes would give the requisite data. Far from it. It is known that the prognosis of duct cancer after operation is good, and that of encephaloid is extremely bad, while cases of very chronic scirrhus may live for perhaps 20 years or so. It will be necessary, then, to compare only cases of carcinoma of the same type. Further, it is absolutely necessary that every case should be submitted to a pathologist for histological examination, in order to be certain that the case was really one of the type under consideration. Otherwise what possible evidence can we obtain, in a case that has not been operated upon and which has been reported as cured by some non-operative measure, that it was a case of carcinoma at all? Again, the stage of the disease in the two classes when they come under treatment must be comparable. More or less sound conclusions could be drawn from data that dealt with cases that came under treatment within the first five months, say, after the onset of the disease, in every one of which a small portion of the growth had been removed and certified by an adequate pathologist to belong to the type under consideration; and, further, the number of cases in either class that were alive at the end of five years would be good material for conclusions. It is true that some deaths might have occurred from accidents or intercurrent disorders, but we may assume that the proportional frequency of such deaths would probably be about equal in each class, those that have undergone operation and those that have not. Even with the most careful precautions against error we must always remember that we are dealing with different patients whose vital resistance is different. But if the data we have indicated could be obtained the method of dealing with them would be as follows. Say that in Class A, those which have undergone operation, there are 5000 cases, which we may denote by (A), and that 500 of these are alive at the end of five years, we can represent this 500 by (AL). Then $\frac{(AL)}{(A)} = \frac{500}{5000} = 10$ per cent. And say that in Class B, those which have undergone no operation, there were 4000 cases, denoted by (B), of which (BL), say 80, cases were alive at the end of five years. Then $\frac{(BL)}{(B)} = \frac{80}{4000} = 2$ per cent. Such a result would be strong evidence in favour of the treatment to which Class A was subjected. But conclusions can only be drawn by comparing the ratio $\frac{(AL)}{(A)} : \frac{(BL)}{(B)}$, and even then the conclusions will be misleading if there has been any selection of cases; if, for instance, the less threatening cases are submitted to non-operative treatment.

Enough has been said to show how difficult it is to obtain the requisite data to which to apply statistical methods in this particular instance selected for consideration. It is not the fault of the methods, but of the observations, which can be so seldom made in the necessary form. Dissimilar cases are put into the same class (for instance, duct cancer with encephaloid) or dissimilar classes of cases are compared with each other rendering the deduction valueless. The general lesson to be enforced is this. Statistical research, like any other branch of scientific investigation, involves difficulties of two orders—the material and the methodological. Most of us appreciate the latter, and feel that experience in the use of mathematical notation is required. But it is equally necessary that mathematical analysis should be informed with exact familiarity with the material peculiarities of the data. Both kinds of knowledge are necessary to reach truth by the statistical path, and even to avoid error. For these reasons the presence of eminent statisticians is welcome upon the Interdepartmental Committee appointed to settle the forms which the records of medical practitioners under the Insurance Act shall take.

◆

Adequate Isolation Hospital Accommodation.

SOME little time ago we were asked by a correspondent to state briefly the factors which should be considered in arriving at a conclusion as to whether or not the isolation hospital accommodation of a district is adequate for the needs of the population it is intended to serve. The answer to this question depends upon various considerations, among the most important of which are: the character of the district, whether urban or rural; the rate of increase of population; the housing and habits of the people; and the amount of intercourse with other places from which infectious disease may be introduced. In most districts hospital accommodation is provided for cases of scarlet fever, diphtheria, enteric fever, and cerebro-spinal fever. For these four diseases, 1 bed for every 1000 inhabitants may be accepted as a rough estimate, though it cannot be regarded as a definite standard. Such a provision is not likely to be found excessive, and will not suffice for the accommodation of all cases during epidemic periods. The adequacy of hospital accommodation will, of course, depend not merely upon the aggregate number of beds, but also upon the manner in which they are arranged in wards. As a general rule it is necessary to have separate pavilions or ward-blocks for each disease admitted to hospital, but an isolation block containing a number of small wards separately entered from the open air is very useful. Accommodation of this nature can be employed for the simultaneous isolation of cases of different diseases; for keeping doubtful cases under observation; for the segregation of complicated or delirious cases; or as private wards for paying patients.

If it is intended to isolate cases of measles and whooping-cough many more beds than 1 per 1000 of the population will be required, but these diseases are seldom removed to hospital on a large scale as the utility of such a measure is still doubtful. Pulmonary tuberculosis is now generally treated in sanatoriums or hospitals belonging to sanitary authorities. The schemes in force for the prevention of the disease are not uniform in character. In some districts only early cases are admitted to the sanatorium, sometimes for short periods as an educational measure or for more prolonged open-air treatment. In other districts late as well as early cases are taken into hospital or sanatorium. No general standard as to the number of beds required is therefore of much value; the needs of each district can only be estimated by consideration of all the various factors concerned.

Every sanitary authority should make provision for the isolation of small-pox. They may do this by themselves erecting a small-pox hospital or by arranging with some other sanitary authority for the use of a certain number of beds when required. The cost incurred may be regarded as the price which the public have to pay for what is known as conscientious objection to vaccination. The modern possibilities of communication by means of motor ambulances render it practicable for a single small-pox hospital to serve the needs of a large area. It is important that the following conditions, which were laid down by the Local Government Board in connexion with small-pox hospitals, should be complied with. The site must not have within a quarter of a mile of it either a hospital, whether for infectious diseases or not, or a workhouse, asylum, or any similar establishment, or a population of as many as 200 persons. It must not have within half a mile of it a population of as many as 600 persons, whether in one or more institutions, or in dwelling-houses. Even where these conditions are fulfilled, a hospital must not be used at one and the same time for the reception of cases of small-pox and of any other class of disease. It is impossible to estimate the number of beds that may be required for the isolation of small-pox during epidemic periods. The site should in all cases be sufficiently large to admit of rapid extension of the hospital by the erection of temporary buildings, and the administrative portion should be upon such a scale as to suffice in the event of such extension of the ward accommodation becoming necessary.

SCOTTISH BOARD OF HEALTH: CONSULTATIVE COUNCILS.—The consultative councils set up under the Scottish Board of Health Act have appointed the following Chairmen and Vice-Chairmen:—Medical and Allied Services—Chairman: Sir Donald MacAlister, K.C.B., M.D.; Vice-Chairman: Norman Walker, M.D. National Health Insurance—Chairman: W. Thomson; Vice-Chairman: Thomas J. Addly. Local Health Administration and General Health Questions—Chairman: Sir Thomas Munro, K.B.E. Highlands and Islands—Chairman: Her Grace the Duchess of Atholl, D.B.E.

Annotations.

"Ne quid nimis."

NEW STAFF OF OUTDOOR MEDICAL OFFICERS OF THE MINISTRY OF HEALTH.

IN connexion with the appointments for medical officers which the Ministry of Health announce in our advertising columns this week the Ministry supply the following particulars which may be of interest. The new staff will include both whole-time and part-time medical officers. Each whole-time officer will be stationed in the area in which he works. Particulars as to the part-time appointments will be announced later. The duties of the whole-time officers will be partly clinical, partly administrative; of the part-time officers clinical only. The clinical duties of the medical officers will consist in examining insured persons referred to them by Approved Societies or doctors, in advising the societies and doctors on questions of incapacity for work, and in advising doctors on questions of diagnosis and treatment. The clinical duties will thus combine those of referee and consultant. For cases of special medical difficulty specialist advice as to diagnosis or treatment will be made available for the assistance of the medical officers. The administrative duties will include examining health insurance medical certificates, records, reports and prescriptions, and making inquiries of insurance practitioners respecting any points arising on these or arising out of the examination of insured persons. The medical officers will also make such other inquiries and take such action in connexion either with the work of the Insurance Medical Service or with other branches of the work of the Ministry as the Ministry may from time to time require.

The Minister proposes to appoint in the first instance 18 whole-time officers for England and 3 for Wales. In addition there will be a small number of supervisory posts. It is contemplated that this number of whole-time officers may be increased (with a corresponding reduction in the employment of part-time officers) as soon as sufficient experience has been gained of the working of the arrangements. Although particulars of the part-time appointments are not yet available, it may be of interest to state that the work of part-time officers will be arranged, so far as the nature of the case permits, in definite half-day sessions at fixed centres; in the more remote parts of the country it will be necessary to employ doctors specially for single cases. Sessions will be held at the various centres at such periods (weekly, fortnightly, or monthly) as may be found necessary to deal with the flow of cases. So far as it can be avoided, a practitioner working part-time will not be called upon to examine cases within the district in which he ordinarily practises. The Minister is appointing a selection committee (of which the personnel will be announced shortly) to consider all applications for the appointments which are now advertised and to make recommendations to him.

SUGAR-BEET GROWING AT HOME.

LAST week a prospectus was issued to the public inviting subscriptions to a large sugar-beet enterprise in this country. With the financial prospects of this concern we have nothing to do, but a leaflet was enclosed in the prospectus setting out some facts which deserve very careful attention as bearing on the future food-supplies of this country. The promoters state that this leaflet forms part of the prospectus, but add that it was issued by the British Sugar-Beet Growers' Society, an association, we may add, supported by eminent agriculturists, economists, and scientific men. This society regards the development of sugar-beet growing as a regenerating influence in agriculture. It is claimed that increased production will result from the introduction of sugar-beet as a rotation crop. One well-known authority states that we can grow beet in England just as well as it is grown on the continent; 12 to 18 tons can be produced per acre, yielding 15 to 17 per cent. of sugar. Wherever the sugar-beet industry has been pursued we are told there has been a better agriculture, there has been more stock, there has been no supplanting or diminution of grain crops, and, finally, there has been increased employment and a greater state of prosperity for the agricultural community. An interesting fact about the beet plant is that it does not in any way exhaust the soil, the sugar being formed in the leaves from the carbon dioxide in the air and the moisture in the ground and transferred to the roots. This sounds a simple synthesis, but one which the chemist so far has not been able to effect. Sugar-beet, whether it is used for its sugar or not, is stated to provide the stock and dairy-farm with a valuable food, and after the extraction of sugar the remaining pulp, representing 50 per cent. of the original root, is highly nutritive to cattle. Experiments have shown that beet-pulp when fed to steers resulted in an approximate gain of 70 pounds per month in weight, and when fed to dairy cattle greatly increased the yield of milk. Finally, we are told that the establishment of the sugar-beet industry in Great Britain will do more to revive the prosperity of our shires and villages than any other possible agency. These authoritative statements are surely of the greatest national importance, and should receive serious and widespread consideration, with the view of getting to work without the slightest delay.

MENINGEAL SYNDROME IN SUNSTROKE.

IT may not be generally known that in severe cases of sunstroke the cerebro-spinal fluid shows marked changes. The fact is of practical importance, for ignorance of it might lead to the diagnosis of meningitis. As long ago as 1903, a French clinician, Dopter, found that, while in mild cases of sunstroke the cerebro-spinal fluid is clear, of normal tension, and does not contain cells, in severe cases it is cloudy, of increased tension, slightly albuminous, and contains cells of variable number. At first there is polynucleosis, then lymphocytosis is gradually established. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Jan. 11th, MM. J. Desqueyroux and Lartigaut have reported the following case:—

> A chauffeur, aged 18 years, was admitted into hospital on August 20th, 1919, for obstinate headache. A fortnight before he made a long journey under a hot sun. His face, neck, and hands became erythematous for a few days and then desquamated. On August 19th, he was again exposed to the sun under the same conditions and suffered from severe headache which obliged him to lie down. On admission he answered questions well and had no mental symptoms. The tongue was foul, the pulse was good but a little slow (60), and the temperature 103° F. He complained of persistent headache. There was stiffness of the neck in the movements

of flexion and extension, but movements of rotation were normal. Kernig's sign was marked, and the meningeal streak was persistent. The reflexes were normal, but the pupils responded sluggishly to light. Lumbar puncture was immediately performed and yielded clear fluid, not under increased tension. On centrifugalisation the deposit was slight, but microscopic examination showed undeformed red corpuscles and numerous cells, about 40 to the field. The leucocytes did not appear altered; their outlines were clear, their nuclei intact, and they preserved their tinctorial affinities. The formula was as follows: Polynuclears, 49·5 per cent.; lymphocytes, 3 per cent.; and large mononuclears, 47·5 per cent. The amount of albumin was greatly increased. Neither direct examination nor cultures showed any microbes, and the Wassermann reaction was negative. Next day the temperature fell to 99·5°, and recovery ensued.

The meningeal symptoms in this case are noteworthy, being more marked than is usual in sunstroke. The conditions found in the cerebro-spinal fluid did not altogether correspond to those described by Dopter, though, as stated by him, the puncture immediately relieved the symptoms. He did not find large mononuclear cells in any of his cases. The intact condition of the leucocytes in the cerebro-spinal fluid is an important diagnostic point. They differ entirely from those found in the ordinary forms of meningitis. The conception of "aseptic meningitis" with intact leucocytes has previously been introduced by Widal. He noted these in the "aseptic puriform meningitis" which occurs in syphilis of the central nervous system. MM. Desqueyroux and Lartigaut attribute the meningeal irritation, a veritable aseptic meningitis, to a phlogogenic influence of poisons accumulated in the organism as a result of the sunstroke. The accumulation is particularly marked in the cerebrospinal fluid. This fact, according to Dopter, explains the curative action of lumbar puncture, which both abolishes the high tension and removes a certain quantity of the poisons.

AMERICAN ANTI-TYPHUS WORK IN POLAND.

IN fighting typhus in Poland great activity was shown last autumn by the Polish Typhus Relief Expedition of the United States Army. This expedition was commanded by Colonel H. L. Gilchrist of the Medical Corp, U.S.A., and news about it has come to us in his reports.[1] He had some 30 officers and 420 men with him, and 32 trains brought over from Coblenz to Warsaw the stores bought by Poland from the American Expeditionary Force, and those contributed by the American Red Cross. Amongst the stores are mentioned 1000 tons of soap and 1,000,000 suits of underclothes. The American officers were posted to districts and worked through the Polish medical health officers. They established field columns which travelled about the country with laundry and disinfecting plants; where they had operated there were no more cases of typhus. The work done by the Americans was largely educative; they were training the Poles to do the work for themselves, that they, the Americans, might get home. They had also to commend their work to the people. There is evidence that they succeeded. Thus at Wlodawa it is observed that "much opposition was at first encountered, and the assistance of the military was required to get the people to the bathing and delousing plant; conditions have so changed it now requires the assistance of the military to keep them away. The people realise the necessity of the work and are coöperating in every way." 28,000 people are, on Nov. 15th, reported to have been washed and deloused. It is to be regretted that operations were begun so late. In the spring 40 field columns will be in action. Each sanitary train comprised 20 specialists, to superintend the bathing and delousing of 800 people daily. Petrol ran short, which delayed work, a motor repair park and chauffeur's school was established, a dentist arrived, and a quarantine cordon was established on the Eastern border. With all this food distribution was never forgotten, it was of so great help in fighting typhus. A most creditable record of industry, good organisation, and philanthropy.

THE OPERATIVE TREATMENT OF CANCER OF THE LARYNX.

THE history of external operations for the removal of malignant disease of the larynx dates from 1870, when Czerny showed by experiments on dogs the possibility of total laryngectomy, and Foulis collected 11 years later 25 cases of this operation, none of which had survived for 12 months. In consequence of these bad results an attempt was made to treat the disease by laryngo-fissure, but with no better success, for in 1887 P. Bruns collected 19 cases with 16 local recurrences and 2 immediate deaths. The illness and death of the German Emperor Frederick in 1888 stimulated interest in the subject. The importance of Krishaber's division of laryngeal malignant growths into intrinsic and extrinsic became generally recognised, and the work of Butlin and Semon established the operation of laryngo-fissure or thyrotomy, which is now acknowledged in Great Britain as the operation of choice for intrinsic cancer which has neither spread extensively to the upper aperture nor penetrated beyond the cartilaginous framework of the larynx. Semon, in 1907, reported 24 cases with 1 death and 3 recurrences, while Sir StClair Thomson reported in 1919 38 cases in his own practice without a death and with 9 recurrences. It will be seen that these results compare very favourably with operations for malignant disease in any part of the body. The important point is early diagnosis, which can usually be made easily enough if only patients be submitted to expert examination on the appearance of the one early symptom, which is hoarseness. Unfortunately, and especially in hospital practice, a large proportion of cases are not seen in time for treatment by laryngo-fissure, and the only alternatives are palliative treatment, which may include tracheotomy and gastrostomy, and laryngectomy; this operation is also the only one available for cancers which begin extrinsically, if we except a few localised growths of the arytenoid and epiglottis, which may be removed by partial operations. Hemilaryngectomy is seldom performed now in this country, principally because it does not permit the air-passages to be shut off from the wound area, a modification which has considerably lowered the mortality of total laryngectomy. It still remains true that the majority of cancers of the larynx reach the surgeon too late for removal by any operation. Total laryngectomy is a very severe operation, and cases should be carefully selected with regard both to the general health of the patient and the local condition. The growth is generally more extensive than appears on laryngoscopic examination. Any considerable glandular involvement is a contra-indication; so also is the invasion of a large part of the pharyngeal wall, though there have been a few successful cases of removal of the pharynx after preliminary gastrostomy. However, the results of the operation are steadily improving, and its position is now well established. In reviewing statistics from abroad it must be remembered that laryngectomy is often performed for cases which would be treated by laryngo-fissure in this country. Thus, Crile, in 1912, reported 24 cases with 2 deaths from operation, but does not use laryngo-fissure; Botez, of Barcelona, in 1914, collected about 200 cases and reported 17 per cent. of deaths, 52 per cent. of recurrences, and 20 per cent. of cures. Chevalier Jackson, who performs laryngo-fissure for intralaryngeal cancer, reported in 1906 that, of 29 cases of extrinsic cancer, he did 8 laryngectomies with no deaths due to the operation, 3 recurrences, and 3 cures at the end of 12 months (1 case too recent to report and 1 lost to view); and in England F. G. Harvey reported 6 cases in 1901, of which 3 were successes. It is being increasingly recognised, as the result of experience, that after this operation patients are *not* reduced to a miserable existence, to which death would be preferable. On the contrary, they can swallow without discomfort or difficulty, and most of them learn to utilise the air of the mouth and pharynx to produce a whisper easily understood, or can do so with the aid of a tube leading from the tracheal opening to the mouth. Sir Charters Symonds, in a paper which we publish in the present issue of THE LANCET, gives a description of four patients who have survived in comfort and happiness and done useful work for 8, 12, 15½, and 22 years respectively; it is to be hoped that this article will encourage doctors to submit suitable cases to operation before it is too late. Sir Charters Symonds does not give any account of the remainder of his cases of laryngectomy, and the publication of these would prove interesting, as also would a description of the details of his operative method, for the technique of this operation has by no means as yet been finally determined.

---

RECENT ADVANCES IN VETERINARY SCIENCE.

THE work of the Division of Veterinary Science, described in the annual report of the College of Agriculture and the Agricultural Experiment Station of the University of California, has been interesting and instructive. The diagnosis of tuberculosis by the complement-fixation test, however successful in man, has proved unsatisfactory in animals; 9·3 per cent. of positive results were obtained in non-tuberculous cattle, and the test proved of no value in the diagnosis of tuberculosis in 20 hogs. It is stated to have been shown by experiments in the field that tubercle bacilli from diseased cattle became harmless in 17 days in dry weather, whereas they retain their virulence for a long time (94 to 171 days) when exposed to rain and moisture. In water-holes tuberculous material was found to remain infectious still longer, in one case for 687 days and in another for 548 days. These results have an important bearing on the disinfection of the surroundings of a tuberculous cow, for any medium which may contain infected material should obviously be freed from sensible moisture. Hypochlorite solution is largely used in disinfecting the stalls of tuberculous cattle, though wholly favourable conditions for its effective action seldom exist; nevertheless, the mechanical removal of discharges and the use of disinfectants on general principles is a sane and safe procedure. Other experimental results recorded in the report include the beneficial effect of sour-milk treatment in coccidiosis of chicks and entero-hepatitis of turkeys, the detection of avian tuberculosis by the intra-dermal test, and the expulsion of intestinal round worms from fowls by the use of 1 lb. of tobacco-dust to 50 lb. of dry mash, or a dose of 1 lb. of tobacco-dust per 100 birds. Investigation of preparturient paralysis of ewes, a troublesome disease from which many losses occur, did not reveal its cause; but as a preventive measure it is advised that the amount of dry food given to ewes during the last months of pregnancy be limited, and that they be made to rustle for their food in order to gain plenty of exercise. An interesting affection of rams denoted by enlargement of one or both testicles, and known locally as "big ball," was found post mortem to involve the whole of the genito-urinary tract and to be due to the *Bacillus pyogenes*, which produced pus and necrosis of soft tissues. A contingent of these rams, not visibly affected, or apparently recovered, only got 33⅓ per cent. of the ewes in lamb. Infection appeared to occur through the urethra. A farm is kept where students may see demonstrations of the methods of clean milk production. It is here that science ought to be able to produce excellent results without greatly upsetting or disorganising present operations. Cleanliness of cowhouses, cows, milkers, properly constructed milk-cans, and care in the distribution and storage of milk are matters of intelligence and industry, and cow-keepers, farmers, and dairymen can secure much more favourable conditions by the exercise of watchfulness and zeal.

A HOSPITAL FOR THE METROPOLITAN POLICE FORCE.

IN a report recently made to the Home Secretary by Sir C. F. Nevil Macready, Commissioner of the Metropolitan Police, it is stated that a committee, under the chairmanship of Sir Hamar Greenwood, has recently had under consideration the whole question of the medical treatment and hospital accommodation for the Force, which seemed capable of some improvement. It is hoped that in the near future the Force may be in possession of a hospital to meet the needs of all ranks, which will go far to put an end to the present system, under which officers and men requiring treatment are often kept for long periods before being able to obtain admission to one or other of the great hospitals of the metropolis.

THE BACTERIOLOGY OF TUBERCULOSIS OF THE SKIN.

IN the last number (Vol. XXIII., No. 2) of the *Journal of Pathology and Bacteriology* Dr. A. Stanley Griffith describes the results he has obtained in the examination of 52 strains of tubercle isolated from cases of subcutaneous tuberculous abscess (scrofulodermia) occurring in Middlesbrough. In 32 instances the organism was of the human type, in 20 of the bovine type, and in testing the virulence of these cultures he made the interesting discovery that 13 per cent. of the former and 20 per cent. of the latter were of definitely low virulence. Hitherto these "attenuated" strains of tubercle bacilli have hardly ever been found in man except in lupus, and it is worthy of note that seven of the eight cases of scrofulodermia from which they were obtained were suffering or subsequently suffered from some form of lupus. In the magnificent series of 1068 fully tested cultures of tubercle bacilli from human disease which Dr. Griffith and his collaborators have examined during the last ten years, these "attenuated" strains have occurred 46 times—in 36 out of 45 cases of lupus, in 8 of 52 cases of scrofulodermia, once in a cervical gland, and once in an intermuscular abscess; 24 have proved human and 22 bovine in type. We could wish that all bacteriological facts rested on such ample and strictly comparable data.

THE STORY OF SALVARSAN.

IT is possible to take the story of the war emergency in organic arsenical compounds one stage further back than was done in our leading article last week. In September, 1914, Dr. W. H. Willcox was consulted by the Board of Trade in regard to the serious situation which had arisen, no salvarsan being then available in England. Dr. Willcox, in collaboration with Professor Sir Herbert Jackson, F.R.S., and Professor A. W. Crossley, F.R.S., carried out a laborious investigation on samples of kharsivan submitted by Messrs. Burroughs, Wellcome and Co., as a result of which it was established that this product, toxicologically and clinically, was practically equal to salvarsan. Their report was issued on Oct. 24th, 1914, and following upon it kharsivan was placed on the market. Afterwards the routine testing was handed over to the Medical Research Committee.

THE Minister of Health has added to the Committee on Medical Records Mr. G. S. W. Epps, F.I.A., to represent the department of the Government Actuary.

THE house and library of the Royal Society of Medicine will be closed from Thursday, April 1st, to Tuesday, April 6th, both days inclusive.

COMPLIMENTARY DINNER TO DISTINGUISHED CHESTERFIELD MEDICAL MEN.

A complimentary dinner was held under the chairmanship of Dr. R. A. M. L. McCrea on March 11th by the medical profession of Chesterfield and district in honour of Sir Josiah Court, recently knighted, and Surgeon-Major A. W. Shea, D.S.O. Sir Josiah Court, in reply to the toast of his health, told a story typical of student wit. At Guy's in his student days Partridge, the famous surgeon, had a horse with a very long neck; so the students christened it "Longus colli"! Later he got another horse, and this one happened to have a very broad back. It was promptly dubbed "Latissimus dorsi"! In course of time this horse also disappeared, and he got another which was thoroughly well built and presented nothing upon which to "hang a label." However, the student ingenuity was not to be beaten, and one day a super-wit conceived the delightful name of "Os innominatum," by which title the horse was ever after known. In responding to the toast of "The Visitors," Professor Arthur Hall congratulated Surgeon-Major Shea on his recent honour, and pointed out that he was the senior past student of the Sheffield School of Medicine to gain a distinction on active service. A review of the distinctions gained during the war by members of the school showed a very fine record: one V.C., one C.M.G., two D.S.O.'s, one M.C. with bar, five M.C.'s, seven mentioned in despatches. The foreign decorations included the Croix de Guerre (won by a woman) and the Order of St. Sava of Serbia. The actual percentage of honours amongst the 254 old students who joined the school between 1888 and 1913, and are still living and in practice, came out, said Professor Hall, to little short of 8 per cent.

THE EGYPTIAN LUNACY DIVISION REPORT.[1]

THE review of the Report of the Lunacy Division from Egypt is very full and informing, agreeing in these respects with the last report.[2] There is great overcrowding in the institution, and, as a consequence, the premature discharge of patients results in relapse or recurrence of mental disorder, and, what is worse, we have criminal attacks of partially recovered patients, who have no longer to be treated as ordinary lunatics but as criminal lunatics. These are the salient features of the document.

The Need for More Asylums.

Dr. J. Warnock, the head of the lunacy work, sketches out some big plans as to other asylums which should be started as soon as possible. The idea that the lunatics in Egypt were very imperfectly provided for was perceived by Lord Cromer, who also recognised that there was not only a want of provision for patients, but (which, he said, was a much more important thing) a want of financial means to carry out any large measure of reform. Dr. Warnock considers that, besides another large asylum somewhere in the neighbourhood of Alexandria, there should at least be an asylum for male criminal lunatics; also an asylum for chronic, evidently incurable, but quiet lunatics, and that proper separate provision for European lunatics is needed. He also thinks that reception wards should be provided, probably in association with general hospitals, in various provincial towns. The central reception-houses should certainly be in Cairo and Alexandria, but provincial asylums also are necessary. When it is reckoned that not one-fourth of the insane in Egypt can possibly be cared for in the present asylums, it will be seen that Dr. Warnock's suggestions are quite reasonable. But, as in Lord Cromer's time, the financial difficulties will probably hinder the development of this scheme.

A short special note is made of the military asylum which was established to meet insanity occurring in the troops, as well as of the asylum at Abbasiya, which receives patients of both sexes, chiefly from Cairo and the neighbourhood, including criminal lunatics. At Khanka a certain number of the more quiet patients—all males, by the way—are sent from Cairo. At this asylum the majority of the non-city dwellers are received, the result being that a different class of patient and a different class of disease is met with in the two asylums.

There was during the last year a great increase in the number of female patients. Provision of accommodation for several classes of paying patients has steadily progressed. As has been noted before in these columns, the lunacy reports, both by Dr. Warnock and Dr. H. W. Dudgeon, are models of clearness and accuracy. All details as to expenditure are given, and the scientific work is not overlooked, though during recent years it has been greatly hindered by war conditions. The death-rate is high; as Dr. Warnock points out, the rate is 21 per cent. in Egyptian asylums.

Chief Causes of Insanity in Egypt: the Prevalence of Pellagra.

Pellagra again is represented as the chief cause of the insanity met with in Egypt, and in respect of the high mortality a special study has been made as to the relationship of pellagra to diet. This is referred to later. As to the overcrowding, in April, 1919, there were 2075 lunatics resident, whereas there was only accommodation for 1581. This leads to a high mortality-rate, a high disease-rate, a high accident-rate, and a low recovery-rate. The British staff, both medical and lay, is small, and was reduced by men being called up for war service.

In the special hospital for soldiers, during the year 125 men were admitted. Of these only five died. In the 125, dementia præcox is represesented by 27, delusional insanity by 25, melancholia 19, mania only 7. Most of the other forms of insanity were represented by quite small numbers. Nothing very noteworthy is said as to the causation of these cases, but heredity is given as being evidenced in 39 of the patients.

---

[1] Report of the Ministry of the Interior, Egypt, Lunacy Division, 1918, at Abbasiya and Government Hospital for the Insane at Khanka.

[2] See THE LANCET, 1919, i., 117.

Of the patients admitted as criminals, pellagra produced 8. Theft and attempted murder were the chief crimes. There were under observation during the year 404 criminal men, 35 criminal women. 380 patients were released before recovery to make room for more acute cases. There is always a rise in the admission-rate in both hospitals for the insane when warm weather begins in April, and the admission-rate falls with the rising of the Nile and the onset of cooler weather.

As to the forms of insanity, pellagra ranks first, alcohol and epilepsy are also potent influences. General paralysis of the insane produces a good many patients among town-dwellers, so there is a much larger proportion of such cases at Cairo than at Khanka. Both men and women are represented, more women in proportion to men than are found in English asylums.

An interesting table shows the various areas in Egypt which produce the largest number of patients suffering from pellagra. Pellagra accounts for 23 per cent. of the female admissions and for 35 per cent. of the deaths among the women. Hashish produces some cases, these coming chiefly from Cairo.

Treatment : the Absence of Restraint.

A report is given of the treatment and the number of patients who are artificially fed. Again the astonishing fact is brought out that during the year no restraint whatever was used. There were very few accidents, and these only of a very trivial kind. The Wassermann test was applied at the Government pathological laboratories, and the results are certainly remarkable if they are to be taken as definite evidences of syphilis. Of the cases of general paralysis of the insane one is surprised to find that only 62 per cent. of the males gave a positive reaction, whereas 83 per cent. of the females gave a similar reaction. In other forms of insanity, especially those coming from Cairo, a very large proportion of positive reactions occurred. For instance, in cases of pellagra 30 per cent. of the men, 22 per cent. of the women, gave a positive reaction. Of 554 cases of all varieties of insanity admitted, who were tested, 28 per cent. gave a positive Wassermann reaction. This certainly is a very astonishing result.

The Government Hospital at Khanka.

At Khanka Dr. Dudgeon also had overcrowding. Here much development is proceeding, though this was delayed to a certain extent during the last four years in consequence of the war. Not only have further buildings been developed, but a great deal has been done in the way of irrigation and tree-planting, so that this desert place is becoming an oasis.

Few hypnotics were used, and no seclusion, the large grounds and out-of-door occupations being found sufficient provision for discipline. Of course, the great advantage of Khanka over Cairo is that there is a large agricultural estate. Though Dr. Dudgeon was short-handed in the matter of staff, he managed admirably. The farm has been a financial success, besides supplying an enormous amount of useful food, both for Cairo and for Khanka.

Influenza, which was epidemic, added greatly to Dr. Dudgeon's work. Besides this, he reports that there were 30 cases of a febrile disorder which he took to be dengue.

His report upon pellagra is disappointing reading. He said little good, if any, followed any form of treatment, although every variety was tried. The symptoms were taken and dealt with one by one, and yet the patients gradually died. He says emphatically once a sufferer from pellagra always a sufferer; that though there may be remissions—in some cases prolonged remissions—yet he is inclined so think the disease always recurs and, sooner or later, ends in death.

He reported four cases of datura seed poisoning. This is a new form of poisoning to British observers.

A most interesting table is given as a result of the examination of the stools of 80 consecutive cases for parasites. Of these, 49 gave positive results for various types of worm, ascaris lumbricoides heading the list with 25; ankylostoma, 8; bilharzia, 5; oxyuris, 5; trichocephalus, 4; and distoma hepaticum, 1.

Admissions and Discharges.

The usual tables of admissions and discharges are given. Of the 365 admissions, 72 owed their insanity to pellagra, and 71 to the abuse of alcohol or drugs. There were more maniacal cases here than at the parent institution. Very interesting tables, of purely local interest, refer to the districts from which the various patients were derived. In the tables of treatment a considerable increase in the use of narcotics is recorded, thus contrasting with Cairo hospital. But this Dr. Dudgeon considers to be purely a temporary matter, due to overcrowding.

In Dr. Dudgeon's report we have to notice the most satisfactory tables with details of medical and material administration, and one must congratulate him on the success of his work during trying and strenuous times.

In Part VII. of the report Professor Wilson gives a very full report on asylum diet. Though this is specially made with reference to Egypt, when circumstances make diet especially important, yet the physiological information contained in it has universal application. He recommends the addition of 45 g. of meal and 50 g. of milk to the ordinary ration. As so much more is now understood in reference to the deficiency diets and the vitamines similar observations might be made in British asylums.

Summary.

So that, to sum up, the Report of Lunacy in Egypt is satisfactory as far as the report is concerned. But the wants and the requirements are very great, and, with the disturbed state of the country, it seems that the work of the English administrators is greatly increased. Dr. Warnock, when he was in England recently, pointed out that the position of himself and other Europeans was not free from danger. We trust that the troubles will pass, and that once more there will be steady progress in relationship to lunacy in that country.

APPEAL FOR LIVERPOOL UNIVERSITY.

WITH a vision and courage that cannot fail to command the admiration of all who are interested in higher education, the University of Liverpool has launched an appeal for the sum of £1,000,000. The moving spirit behind this bold venture is the new Vice-Chancellor, Professor J. G. Adami, who, acquainted at first hand with the largesse bestowed upon the universities on the other side of the Atlantic, is seeking to awaken a similar generosity in and around Liverpool.

To mark the inauguration of the scheme a meeting was held in the Town Hall on March 12th. Lord DERBY (Chancellor of the University), who was prevented from attending, sent an appeal which was read at the meeting. It shows that this year the number of students availing themselves of the privileges of the University is more than double the total before the war. As a consequence the resources of the University are strained to the utmost, while each Faculty has had to refuse many students. The immediate needs are more class-rooms, laboratories, and workshops for students in chemistry and physics, engineering and electricity. The library, which may be termed the laboratory of the Arts students, must be enlarged. The great increase in the size of the classes calls for a corresponding increase in the staff of professors, lecturers, and demonstrators; and as students are pouring in from the surrounding districts it is necessary, if they are to enjoy that corporate life which ought to be a feature of all university education, to procure hostels or halls of residence for their accommodation. Provision must also be made for athletic grounds and a well-equipped gymnasium. The appeal concluded:—

"The University of Liverpool has proved its use. It is no longer in the experimental stage. ...... I call upon all in our

community who have its welfare and advancement at heart, upon all interested in the prosperity of Liverpool and of the district served by the University—West Lancashire and Cheshire, North Shropshire, and the counties of Flint and Denbigh, Westmorland, and Cumberland—to respond according to their means."

After an introduction from the LORD MAYOR, the President of the Council, Mr. HUGH R. RATHBONE, proposed this resolution :—

> **"That in the opinion of this meeting the needs of the University are so urgent that it is necessary to make a public appeal for funds to carry on this national work."**

Liverpool University, he said, now stood at the forefront of the modern universities of the world. No doubt the lessons of the war had been responsible for a large part of the increase in the number of students, but the desire for more extensive and higher education had been growing rapidly throughout the country before the war came.

The Importance of University Training.

Professor ADAMI, in seconding the resolution, said that men in Liverpool and elsewhere had been heard to protest that they preferred to have anyone in their business rather than a university man. It was that spirit which nearly lost us the war, the contentment with rule-of-thumb methods and easy jogging along. No business man who had studied the events of the last five years could be in doubt as to the vital importance of enlarging and equipping our modern universities. It was only when the war was half-way through that our scientific men were withdrawn from the army and the universities all over the country called upon to make up for lost time at enormous cost. Students were now pouring into the University. Before the war the high-water mark was 1178. Now they had more than 2500 students. The University was full to bursting point and the staff was too small to deal with the huge classes, and their accommodation was altogether inadequate. The University already had a notable faculty of arts, but to-day they found the students coming to them were eager for increased knowledge in the principles of great scientific industries. With the chemical industry close to their doors they must do their best to meet the urgent cry for training in chemistry. Students were also asking for higher instruction in engineering—electrical and naval. They wanted laboratories for organic and inorganic chemistry, physical chemistry, colloid chemistry, and electrolytic chemistry. The laboratories, in existence since 1881, were lamentably inadequate for present needs. For new chemical laboratories £350,000 was required, and about £100,000 was wanted for the electrical engineering department. These were only a few of the urgent needs. They had to attend to the corporate and social life of the students. The students' union was only a quarter of the size required. The variety of commercial interests that now centred in the vast trade of the city demanded that they should train their young men in such practical studies as tropical medicine, oil-bearing sands, petroleum, refrigeration, and various transport industries. The University existed to increase the enlightenment and advance the prosperity of the whole of that part of the country from which it drew its students, and he looked to Liverpool to maintain its reputation for drive and progress.

Sir WILLIAM MCCORMICK, Chairman of the Advisory Committee on University Grants, and Sir WILMOT HERRINGHAM supported the resolution, which was carried unanimously.

Sir JAMES HOPE SIMPSON, General Manager of the Bank of Liverpool and Martin's Ltd., in moving support to the appeal, said that a commercial man did not look so much to a University for the technical training of his future employees as for the development of the qualities and the outlook which best fitted a young man for the responsibilities of a business career.

The Bishop of LIVERPOOL, in supporting the motion, said that if the wage-earning classes were to receive more wages and be given more leisure they must be given higher ideals, so that wages and leisure might be spent aright; and if an enlarged electorate was to exercise its opinions rightly on the great problems of to-day it must be taught to think in terms other than those of self and class.

Mr. C. SIDNEY JONES, the treasurer of the University, announced that promises and contributions amounting to £201,500 had already been received. These included, amongst other large sums, a gift of £25,000 to endow two chairs in engineering, £20,000 towards new chemical laboratories, £20,000 for the School of Social Studies, £20,000 for building and equipment of a special home for education and educational library.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh Post-Graduate Courses in Medicine.

IN connexion with Edinburgh University and the Royal Colleges, special advanced courses for graduates will be held during the summer and autumn terms, and during the summer vacation. These courses include such subjects as clinical therapeutics, tuberculosis, diseases of the blood, renal, alimentary, and circulatory systems, bacteriology, serology, medical and surgical anatomy, special regions of the body, venereal diseases, and child welfare. The individual courses will be held subject to a certain minimum number of graduates entering for them, and in some cases a maximum limit will also be imposed. The teaching will be carried out by teams of physicians and surgeons under the direction of the University professors and lecturers. Arrangements will also be made, if desired, for special instruction in antenatal medicine, psychiatry, and dermatology. Graduates will be allowed to take out more than one course provided that the time-table makes this possible. Each course will be of a thorough and comprehensive nature in order to supply the want of graduates desiring advanced training in a particular subject. Full particulars may be obtained from the honorary secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Edinburgh Royal Infirmary.

The Royal Infirmary of Edinburgh is suffering from the effect of high prices and cost of labour, and additional subscriptions are urgently needed. A special effort to raise £250,000 is announced; the campaign will be launched at an early date, and probably will finish about the end of June, with a week of intensive propaganda, when every available method of publicity will be brought into play. The coöperation of all is heartily invited.

University of Aberdeen: New Professor of Botany.

Mr. W. G. Craib, M.A., has been appointed Regius Professor of Botany in the University of Aberdeen, as successor to the late Professor Trail, whose pupil he had been. In India the new professor acted temporarily as superintendent of the Botanic Gardens in Calcutta, and he was for a time assistant at Kew. Coming to Edinburgh some five years ago, he was appointed lecturer on forest botany and Indian forest trees under Professor Bayley Balfour. During the war he was specially engaged in testing timber used in the manufacture of aeroplanes.

Child-Welfare Work in Scotland.

A conference was held in the City Chambers, Edinburgh, on March 10th, under the auspices of the Scottish Federation of Mother and Child-Welfare Associations, when the subject of the importance of a pure milk-supply was discussed. Attention was drawn to Dr. Addison's statement in the House of Commons that during the year 400 additional child-welfare centres had been established throughout the country and that the infant mortality-rate for last year was 89 per 1000, the lowest on record. In 1906, before the maternity work had been commenced, the rate was 145, while in 1914 it had fallen to 105. Mr. John Fraser addressed the conference on the dangers of impure milk in producing tuberculosis in children. 30 to 40 per cent. of the children occupying surgical beds were thus affected. Ingestion of tuberculous milk might produce various local lesions or, the bacilli passing into the blood, infection might be carried to distant parts, such as the bones and joints. Precautions should be taken to render the milk harmless. The resisting power of better-class children was higher because of their superior nutrition. Dr. J. M. Lauder addressed the conference on the Production and Handling of Pure Milk, urging the establishment of a branch of the Clean Milk Society and the promotion of clean milk competitions. The eradication of tuberculous cows would require time, and he thought it would be reasonable at first to pay compensation to the people whose cows were destroyed. A resolution was carried calling on the Government to re-introduce the Tuberculosis Order and to bring into force the Milk and Dairies Act.

Panel Doctor's Action for Slander Upheld.

A libel action heard on appeal before the Lord Justice-Clerk has excited much interest. Dr. James Wylie, a doctor on the Glasgow panel, brought an action for slander against the general secretary of a local friendly society. The case centred round a certificate of incapacity given by the doctor on a date on which it was understood, erroneously, by the secretary that the patient was still away from home. The secretary thereupon stated in a letter to the Insurance Committee that a certificate had been granted by the doctor without seeing the patient and in contravention of the law. At the first instance Sheriff-Substitute D. J. Mackenzie found that the secretary's letter was defamatory and malicious, and awarded damages to the doctor. On appeal Sheriff A. O. M. Mackenzie reversed this decision on the ground that the occasion of writing the letter was privileged, and that malice had not been proved. The Division finally upheld the first judgment on the ground that the letter had been sent without due inquiry, and that the defender's recklessness in making the charge against the pursuer, without regard to its serious nature and to the want of information on which it was founded, amounted to legal malice, disentitling the defender to plead privilege. The Medical and Dental Defence Union of Scotland is to be congratulated on its successful vindication of the good name of the panel doctor.

March 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

"Carriers" of Scabies.

M. Gougerot has published some careful observations made in the dermatological department of the Hospital St. Louis. It appears that certain people, even if sharing the bed of someone suffering from scabies, do not become infected, being apparently immune from the disease. M. Gougerot has noticed this phenomenon in subjects dark or fair, thin or fat, without being able to determine the conditions which influence their immunity. Moreover, he has observed that some people who do not themselves contract scabies, though exposed to the infection, are yet capable of transmitting it to a third person. For example, a prostitute may transmit the disease without herself suffering therefrom. It seems as if the acarus could live on the skin without penetrating it; the "carriers" do not cease to be contagious until they have themselves been treated for scabies, though they present no lesion whatever. These observations, the accuracy of which are guaranteed by the reputation of M. Gougerot, have raised a good deal of controversy.

The Difficult Position of the Medical Profession in France.

The medical profession in France is at present in the throes of a crisis. The general augmentation of the cost of living consequent on the low rate of exchange has caused a considerable increase in their normal expenses. The prices of commodities, clothes, and instruments have tripled; those of servants, cars, and books have doubled. Fees have had to be increased, but the public, themselves obliged to economise on all those expenses which are not, like food and clothes, immediate necessities, compensate themselves for this increase by sending less often for the doctor. They even try to dispense with his attendance for as long as possible. In many families appeal is made to the medical lore of a relative, or advice is sought from a friend who has been a hospital nurse during the war and is proud to show off her accumulated wisdom. People resort also to proprietary medicines which can be delivered without prescriptions. These proprietary productions have had a considerable boom recently, and a proof of their prosperity is that discussions on their merits are now appearing in political journals. The middle ranks of the profession are the hardest hit. The suburban and country doctors with a family practice are relatively little affected, as are also the eminent scientists whose advice is sought by the rich. But ordinary specialists and practitioners of the better class, whose patients used to be the bourgeois families, see the number of their consultations diminishing to a degree in no way compensated for by their raised fees. At the same time it is on the doctor that the burden of rates and taxes falls most heavily, and he is unable to defend himself, as does the working man, by threatening to strike. In the districts formerly invaded by the enemy the situation is even worse. The Government has called for the coöperation of doctors, who are asked to give their services to people living under miserable conditions in caves and barracks pending the reconstruction of their houses, and unable to pay their doctors adequately. Certain practitioners have been promised fixed appointments, with free provision of motors, tyres, petrol, and surgical instruments. But the organisation is so bad that after a few months, during which they have been unable to obtain tyres or petrol, or to get repairs done to cars damaged by the bad roads, most of them have renounced the illusory advantages promised them and have gone away. Many of the regions in the north of France are thus without doctors, who have come back to join the already overcrowded profession in Paris. Several of them are leading a miserable life there, and one doctor, an officer of the Legion of Honour, was recently heard to announce to his colleagues at a congress his intention of applying for a post as sweeper in the municipal service, so as to be certain at least of a monthly salary for an eight hours' working day.

Strike in the Printing Trades.

Owing to a printers' strike hardly any medical journals have been published for the last fortnight. It is not yet known when work is to be resumed.

An Extension of the Paris Maternity Hospitals.

M. J. L. Breton, Minister of Hygiene and Social Service, accompanied by M. Desmars, Director of Public Hygiene, and by M. Legendre, has visited the asylum of Vesine, which is now empty and capable of accommodating 490 beds. He has decided to take over the asylum as an addition to the maternity hospitals of Paris, which are very overcrowded. Arrangements have been made for 40 beds at least to be ready next week, and the remainder will soon be available.

March 15th.

DEVONSHIRE TUBERCULOSIS COLONY.—At the last meeting of the Devon County Council it was stated that the council was now in a position to establish the tuberculosis colony at Hawkmoor Sanatorium for the training of tuberculous ex-Service men, and also to provide a school for children who had incipient signs of the disease. The Red Cross Society has given £18,000 to the scheme.

DORSET COUNTY HOSPITAL, DORCHESTER.—The annual meeting of the subscribers to this institution was recently held. The medical report was satisfactory, while the financial statement gave the receipts as £5782 and the expenditure as £7538. The committee made an urgent appeal for increased financial support, so that the hospital "could live on its income and not its capital." A special appeal is being made for £7000 for alterations and improvements to the hospital. The British Red Cross Society has made a grant of £2500 towards this amount, and it is hoped that the balance will shortly be raised.

Correspondence.

"Audi alteram partem."

ANÆSTHETISTS' FEES.

To the Editor of THE LANCET.

SIR,—I think the time is now suitable for drawing attention to the inadequacy of the fees which formerly have been offered to special anæsthetists for their attendances at private operations. When it is considered that men with a staff appointment at one or more hospitals often attend for many hours a week, and administer over a thousand anæsthetics a year for charity, proper payment for their skill, which will cover expenses, and yield an income proportionate to the value of their work and experience, is the least desideratum. The major operations command handsome fees for the surgeon, and should also reward the anæsthetist, primarily according to the duration of his attendance, and in some degree according to the quality of his labours.

In addition to these points, the administration of nitrous oxide and oxygen for surgical work, besides being far more expensive in apparatus and outlay than the older methods, is a far greater strain upon the faculties and attention of the administrator than anything else which has yet been attempted. Where this anæsthetic is suggested, a fee of from 15 to 20 guineas is required to pay the administrator commensurately for the undertaking. It ought not to be necessary to point out to the operating surgeons of the day that the requirement of a heavier fee by the professional anæsthetist does not diminish, but enhances, the public estimate of the value of their own performance.

I am, Sir, yours faithfully,
H. BELLAMY GARDNER.

Harley-street, W., March 14th, 1920.

REMOTE EFFECTS OF SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCER.

To the Editor of THE LANCET.

SIR,—The value of a discussion on the remote effects of surgical treatment of gastric and duodenal ulcer, such as that held recently at the Royal Society of Medicine,[1] depends on the comparative results obtained by various lines of treatment, and this to be of real value requires a general agreement on methods. There is at present no real standardisation of treatment; there are those who believe that these ulcers are a local condition, primary and independent of pathological conditions elsewhere; there are others who consider that they depend for their occurrence on some pre-existing infective focus—e.g., in connexion with the teeth, nose, gall-bladder, appendix, intestinal tract, &c. The former class should be content with local excision, the latter must seek for and eliminate the distant focus as well as adopt some local treatment. That there is confusion here is evidenced by the frequently expressed condemnation of excision alone as a cure for gastric ulcer, and the common belief that a permanent cure follows successful suture of a perforated gastric ulcer. Then, while there is general agreement that gastro-enterostomy is the operation of choice for duodenal ulcer, there is wide difference of opinion as to the value of gastro-enterostomy in gastric ulcer (excluding pyloric ulcer), as to the type of case in which to do partial gastrectomy, and as to the methods of performing it (Billroth II., sleeve resection, anterior Polya). Even there is no agreement on the danger or otherwise of the unabsorbable suture. I think these disagreements are due more than anything else to the neglect of the "follow up" investigations, which such a discussion as we have had does much to stimulate. The less we follow up our cases the more rosy our views on our results. I have followed up my gastric and duodenal cases fairly consistently since my first operation some 15 years ago, and though I am satisfied with the immediate results of gastro-enterostomy (my longest run without a death was 105) and of its great value in duodenal ulcer, I am becoming more critical of its value in gastric ulcer unless that ulcer is quite close to the pylorus, and I am doing more partial gastrectomies than I did.

The discussion centred on the late results of gastro-enterostomy, and particularly on the occurrence of gastro-jejunal and jejunal ulcer. I have never seen an instance of a pure jejunal ulcer, and have had only two instances of gastro-jejunal ulcer (found at re-operation) in my own practice. In both cases I found a silk suture adherent at the seat of ulceration. In view of the rarity of gastro-jejunal ulcer and the frequency with which gastro-enterostomy is performed with non-absorbable suture, it seems unreasonable to believe that the single factor of a non-absorbable suture is the cause of this complication. I am inclined to believe that a combination of four factors is necessary: (1) hyperchlorhydria persisting or recurring after operation; (2) an unabsorbable suture; (3) an undiscovered or uncured primary focus causing the original ulcer; (4) an error in technique, in this case drawing the suture too tight. It is well known that tight suturing of muscular tissue leads to local necrosis, and, indeed, is the commonest cause of failure of radical cure of inguinal hernia.

In a recent "follow up" of 50 consecutive cases of gastro-enterostomy, operated on six months ago or longer, I have been able to trace 24 out of 26 duodenal ulcer patients, of whom 19 are completely restored to health = 79 per cent., while of 24 gastric ulcer cases I have traced 19, of whom 12 are completely restored to health = 63 per cent.; of these gastric ulcer cases 2 were known to be cancer and died 6 weeks and 18 months after operation, and 2 others were considered cancerous at operation and are now quite well.

One of the commonest complaints after gastro-enterostomy is a feeling of fullness in the epigastrium directly after food. I believe this to be due to the rapid emptying of the stomach into the jejunum, and I advise all my patients for the first six months to eat small meals very slowly, and to lie down on the left side for half an hour afterwards. It would be interesting to hear the opinion of surgeons as to when we can consider a patient cured after an operation in which the ulcer is neither excised nor otherwise treated. My experience leads me to believe that if complications arise they will show some sign within two years from the operation, and I lay down as a rule, quite arbitrary I fear, that the ulcers must be considered unhealed for six months. I feel sure it is unwise, encouraged by the relief of pain and return of appetite, to allow an early return to a generous diet.

I am, Sir, yours faithfully,
Harley-street, W., March 15th, 1920. H. W. CARSON.

SLEEPING SICKNESSES.

To the Editor of THE LANCET.

SIR,—In the interests of historical accuracy may I venture to demur to the statement in your annotation of March 13th under this heading that at the combined sections of the Royal Society of Medicine in November, 1918, it was agreed to follow von Economo in the use of the word "encephalitis lethargica"? The meeting (which took place in October) was convened to discuss epidemic encephalitis, and the record in the Society's Proceedings is thus entitled. The name "encephalitis lethargica" was certainly employed by some of the speakers at the meeting, but no formal agreement with von Economo's nomenclature was proposed. Compliance in this country with von Economo's practice was a consequence of the benediction given to it by the Local Government Board, and the disuse into which, outside Great Britain, it is rapidly falling is due, not only to the objection of cumbersomeness that you raise, but to recognition of the fact pointed out by the minority in 1918, which has been recently expressed by Professor Chauffard (Académie de Médecine, séance du 17 Fév., 1920) in these words: En raison de la multiplicité des formes récemment décrites de l'encéphalite léthargique, le nom de cette maladie est devenu trop restrictif et *ne répond plus aux réalités cliniques*.

---

[1] THE LANCET, March 13th, p. 598.

If, however, undue attention has been paid to the views of von Economo, it would seem that undue neglect has attended those of Mauthner, also of Vienna, who in 1890 recognised "nona" as a phase of Heine-Medin disease. And it should not escape notice that at the present time there is in Vienna an epidemic of encephalitis that, from the clinician's point of view, is like some of the Australian outbreaks in 1917–18, not lethargic but convulsive. The Viennese physicians appear now to realise that we have to do with a protean encephalomyelitis that is in epidemiological liaison with influenza, as some of us at home have consistently believed.

But it is also interesting to note that the present Viennese cases appear to be indistinguishable clinically from what was once described as "Kriebelkrankheit" and "r(h)aphania," and ascribed to ergot, radish seeds, and sour apples. The contention put forward by me in 1918 (Proc. Roy. Soc. Med., vol. xii., Sect. Hist. of Medicine) that the "Kriebelkrankheit" and raphania were really identical with the protean encephalomyelitis that almost invariably has preceded attended, and followed wide diffusions that we call influenza appears therefore fortified by the course of events.

I am, Sir, yours faithfully,

Wimpole-street, W., March 13th, 1920. F. G. CROOKSHANK.

CIRCUMCISION AND CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 20th, 1919, Mr. H. Tyrrell Gray and Dr. G. R. Pirie, in a most interesting and searching study of this stomach malformation of infants, point out the association of phimosis or preputial adhesions as a possible factor of causation of the events leading to projectile vomiting characteristic of this lesion, whether there be a definite organic or merely a spasmodic block of the pyloric end of the stomach. Later, in the issue of Feb. 21st, 1920, Mr. Joseph E. Adams relates a case where circumcision temporarily relieved all symptoms only to end fatally a week later. I notice in his concluding remarks that granting, as in his case, no actual pyloric lesion or any gastritis was present, and that circumcision temporarily relieved the symptoms, "other factors" of causation are present which one cannot expect to relieve by circumcision.

A case recently came under my care which forcibly shows the value of circumcision and yet raises doubt in the mind as to whether "other factors" are not present in the neuro-muscular mechanism of the stomach which may produce "projectile vomiting" and the train of symptoms associated with congenital pyloric stenosis. A child, aged 3 weeks, was brought to me with every one of the classical symptoms which were so lucidly arranged in Mr. Gray and Dr. Pirie's article. Complete pyloric block was confirmed by radiographic inspection. A very tight prepuce was noted. At operation the pyloric lesion was of the hard avascular type, the mass being as large as a big acorn. In my zeal to ensure success by wide section in the Rammstedt's operation, I punctured the duodenum, which was promptly repaired and reinforced by a piece of omentum. As the infant virtually died on the table, circumcision was postponed. After a struggle the infant survived, and in the second week he put on 7 oz., peptonised milk being used. On the sixteenth day sudden alarming projectile vomiting returned. To eliminate any indiscretion of feeding, albumin water only was given by mouth and saline repeated by rectum. No relief ensued and the child began to fail. I therefore circumcised him at the end of the second day. The vomiting ceased as by magic, and in six hours no further feeds were rejected.

It is now 14 days since circumcision, and the child is well and progressing steadily. Now, in this case, as far as is surgically possible, the muscular and serous coats of the pylorus and the adjacent portion of the stomach and duodenum were cleanly and thoroughly divided, so that spasm at this site was not likely to recur. And yet recurrent "projectile vomiting" recurred until relieved by circumcision.

In opening myself to criticism as to any faulty technique, I ask, "Is it possible for 'other factors' to cause projectile vomiting, such as reversed gastric peristalsis stimulated by a tight foreskin, without necessary involvement and block of the pylorus?" It seems possible, as this infant is alive and well, with no further symptoms when the recurrence of vomiting came on after surgical relief of the original pyloric spasm and obstruction had been secured by section of the muscular coats.

I am, Sir, yours faithfully,

R. ECCLES SMITH, O.B.E., M.B., F.R.C.S.

Barry, Glam., March 17th, 1920.

MYALGIC PAINS AND MANIPULATION.

To the Editor of THE LANCET.

SIR,—Mr. Haldin Davis, in your issue of Jan. 10th, suggests that there is "something in manipulative surgery," and Mr. W. H. Clayton-Greene (March 13th), admits that "the manipulative surgeon possesses some skill which he ...... lacks." May I suggest that the latter should substitute *knowledge* for *skill*. Of course, there is something in manipulative surgery, and it is to be hoped that many surgeons practise this branch of their art. I at least may claim that I have been both practising and teaching it for many years, and I believe that the same is true of other orthopædic surgeons. The trouble is that the teachers of manipulative methods, from Wharton Hood onwards, have failed to secure the ear of the profession as a whole, and that the importance of the study of the physiology of joints and muscles has never been recognised. It is perfectly true that many cases of derangement of the knee-joint can be cured without operation. Why? Because in some of them there has been no injury to the semilunar cartilages at all, and in others the damaged cartilage can be prevented from causing locking of the joint by physical treatment. Mr. Clayton-Greene appears to look upon the bone-setter as endowed with some peculiar mechanical skill which enables him to carry out manipulations which he (Mr. Clayton-Greene) cannot imitate. Surely the fallacy of this myth has long ago been exposed by Wharton Hood. The rules of manipulative methods are simple: first restore a perfectly full range of movement in the joint or joints, and, second, by appropriate exercises, assisted, when necessary, by direct faradic stimulation of the muscles, give these back their full power. Patients with derangement of the knee-joint should only be submitted to operation when continued locking of the joint takes place in spite of the fact that the mobility is full and the muscles strong.

Another condition commonly and successfully treated by the bone-setter is a chronic painful swelling of the ankle. Three times recently have I had to treat such a condition in a patient who had been subjected to prolonged fixation of the joint for alleged tuberculous disease. In each case mobilisation under an anæsthetic, followed by appropriate walking exercises, has effected a speedy cure. Adhesions on the front and outer side of the ankle were the sole cause of the trouble. I claim no special skill in manipulation: all that is necessary is the recognition of the pathology of the lesion and of the fact that interference with the normal physiological action of the foot is sufficient to account for both pain and swelling.

By all means let us have the inquiry suggested, if the bone-setters will agree. But bone-setters are not too anxious to give away the extreme simplicity of their methods, and their attitude to a committee, including surgeons able to sum the methods up, is at least doubtful.

I am, Sir, yours faithfully,

Portland-place, W., March 13th, 1920. R. C. ELMSLIE.

THE EMPLOYMENT OF FEMALE NURSES IN MENTAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—In your issue of March 6th your Scottish correspondent summarised very accurately the last report of the Royal Edinburgh Asylum, but there is, unfortunately, a misstatement in the last sentence. It is there recorded that the male nurses of the asylum had submitted a demand that female nurses should no longer be allowed to attend male patients. As this question is a very important one at the present time owing to the action of the National Asylum Workers' Union, which wishes to abolish this form of nursing, I desire to say that no such action has been taken by the male nurses.—I am, Sir, yours faithfully,

GEORGE M. ROBERTSON, M.D.

Edinburgh, March 15th, 1920.

THE VAGINOTOME.

To the Editor of THE LANCET.

SIR,—Under the above heading Mr. Aleck W. Bourne describes in your issue of Feb. 21st an angled knife for cutting through the vagina after a clamp has been placed in position in radical operations for cancer of the cervix. I am afraid I have forestalled him by some six or seven years. I enclose a photograph (Fig. 1) of an identical instrument,[1] with the exception that mine is double-edged, which I have used for the period mentioned, as many can testify. Nevertheless, I prefer to use, when possible, a cautery-knife.

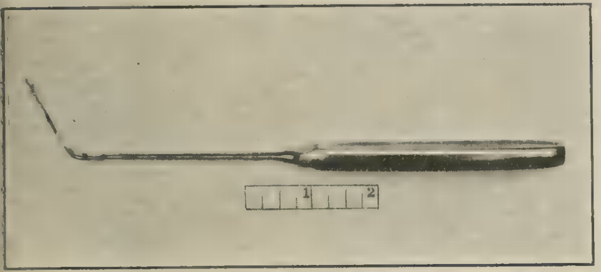

FIG. 1.—Mr. Blair Bell's vaginotome.

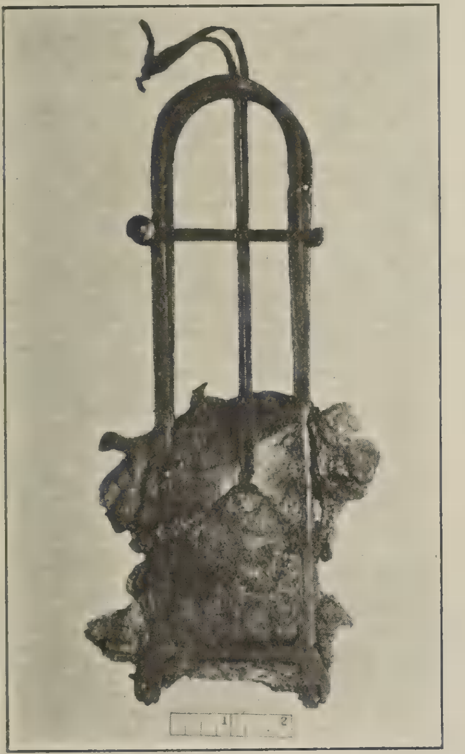

FIG. 2.—Vaginal clamp, with excised specimen.

Perhaps, before someone else invents it, I may be allowed to enclose for reproduction also a photograph (Fig. 2) of my vaginal clamp for use in radical operations for cancer of the cervix. It is only a rough model made in the laboratory, and requires certain obvious improvements when I can find an instrument-maker who can promise to get the work done. I have used this instrument for an even longer period. It embodies, I believe, sound mechanical principles and is easy of application. It will be seen that the specimen, as excised at operation, has been photographed in the clamp before being removed.

I am, Sir, yours faithfully,

Liverpool, Feb. 22nd, 1920. W. BLAIR BELL.

OSTEITIS FIBROSA.

To the Editor of THE LANCET.

SIR,—I was much interested in Mr. N. C. Lake's case of osteitis fibrosa published in THE LANCET of March 6th, and the radiogram is certainly strikingly like that of my case which you reprint with it. The suggestion in the text, however, is that the X-ray appearances would lead one to expect gross cyst formation, and it is implied that this was present in my case. A reference to my article in THE LANCET of Nov. 15th last will, however, show that such was not the case, although it is true that minute cyst formation was found under the microscope. I pointed out in that article that the femur is the common site of non-cystic osteitis fibrosa, and that the reason probably is that cyst formation is a slow degenerative change, and that the weight-bearing functions of the femur call attention to the condition in that bone before cyst formation has had time to occur. The history of Mr. Lake's cases, particularly the first one, is interesting, but there seems no definite evidence that the osteitis fibrosa did not antedate the trauma in both cases. I am, Sir, yours faithfully,

London, March 10th, 1920. E. G. SLESINGER.

INTENSIVE IODINE TREATMENT.

To the Editor of THE LANCET.

SIR,—Having read Dr. T. Bird's interesting note on this subject in THE LANCET of March 6th I wish to add my testimony as to the result of the treatment. I have used the French tincture for some years in rheumatic and arthritic cases with very great success; I cannot call to mind a single case of iodism or any untoward symptoms arising. I usually prescribe at first 2 gr. three times a day immediately after meals, gradually increasing the dose until the patient is taking 10 gr. daily. It is remarkable how the pain and swelling are relieved, and as soon as this occurs I gradually decrease the dose. After a short interval the doses are again gradually increased in old-standing cases. There is not the slightest doubt that the absence of iodide of potassium in the tincture of the French codex enabled the administration of iodine in larger doses and with better results in the foregoing cases than the administration of potassium iodide.—I am, Sir, yours faithfully,

CLAUDE ST. AUBYN-FARRER.

Harley-street, W., March 9th, 1920.

OPERATION UNDER DIFFICULTIES.

To the Editor of THE LANCET.

SIR,—The recent war has doubtless supplied many instances of surgical operations successfully performed under the most unfavourable and apparently hopeless conditions. Yet few, if any, would equal the description and circumstances of "An Operation under Difficulties," reported by Dr. Nathaniel Crichlow in THE LANCET of Feb. 7th. The remarkable and striking success which attended his impromptu efforts, though modestly attributed to the natural immunity of the Solomon Island native, completes a thrilling story of what can be achieved in a surgical emergency. As an example of an emergency operation performed under embarrassing conditions, in the heart of the West African forest at midnight, while a tornado was raging, the following incident, which occurred in the course of the Anglo-French Boundary Commission's survey of the Gold Coast and Ivory Coast Colonies in 1903, may prove of interest. In this case, too, the patient was a native, and his eventual recovery lends support to Dr. Crichlow's view of the natural resistance to septic infection, and possibly shock, displayed by the native races. The circumstances to be faced were not, indeed, as unfavourable as those confronting Dr. Crichlow, for, though the operation was a serious and difficult one, the operator had the advantage of surgical instruments and dressings with means of sterilising, also the uncertain asset of a native dispenser as chloroformist and the unskilled assistance of a French officer as dresser.

---

[1] Made and kept in stock by Messrs. Alexander and Fowler, Liverpool.

The expedition on its return journey from completion of the boundary survey between the Ivory and Gold Coast Colonies had halted on the afternoon of March 8th (1903) at Ngwanda, a small forest village situated near the frontier, and composed of a collection of half-ruined native huts, only one of which was at all habitable for Europeans. At about 7 P.M., during a violent storm of wind and rain, and just as the members of the Commission were sitting down to dinner, the medical officer was suddenly called to see the native cook of one of the French officers. The boy, who was lying on a bed made of carriers' loads in a tiny bamboo hut, complained of great pain in the belly, and had had no action of the bowels for two days. Constipation and belly-ache, for which the "Livingstone Rouser" usually proved quite efficacious, were common enough troubles of daily occurrence among the morning sick. But in this instance it was timely ascertained that the boy had been ruptured for several months, although the condition had never sufficiently troubled him to seek medical advice. Examination revealed a large hernia occupying the scrotum on the right side, and about the size of a fœtal head at term, very tense, and apparently irreducible. Symptoms of strangulation had lasted an hour and he vomited soon after he was seen.

In anticipation of the probable necessity of operation, preparations were accordingly made as quickly as possible. With the patient's hips immersed in a hot bath all attempts at reduction by taxis, even when he was under the influence of chloroform, failed. Operation was therefore at once proceeded with under conditions which seemed anything but hopeful. The walls of the dilapidated hut inclined at an angle and, owing to the increasing force of wind and rain, threatened to overwhelm the occupants at any moment. To avoid such a catastrophe it was necessary to support the frail structure with propping poles as buttresses on the leeward side. Through the scantily thatched roof the deluge of rain beat its way in copious streams at various points during the greater part of the night. The only light for operating by was a reading candle-lamp with reflector. The supply of antiseptics was limited, and eventually the use of boiled rain-water was resorted to. Chloroform was very successfully administered by the native dispenser, and but for his help it would have been impossible to save the boy's life.

The necessary incision was made in the right inguinal region and the bowel was exposed. Though much congested, particularly at the place of constriction, there was no evidence of actual peritonitis or commencing gangrene, and well for the patient that resection of the gut was not called for! There was considerable difficulty in returning the distended and congested coil of gut to the abdominal cavity and in retaining it in place. This was, however, eventually successfully accomplished, and it was possible to attempt a partial closure of the inguinal ring by stitching with sterilised silk-worm gut in the hope of securing a radical cure. There was fortunately no hæmorrhage of any importance during the course of the operation, which the patient bore remarkably well. A small drainage-tube was inserted, the wound was stitched up, dressings applied, and by 1 A.M. the difficult task was over. The boy's pulse was good, he vomited twice during the remainder of a restless night, and his bowels acted at about 4 A.M. Thirst was much complained of, and partly relieved by sips of hot water. When daylight came, as his general condition was quite satisfactory, and it was impossible for him to be properly attended to in such incommodious quarters, it was considered justifiable to risk his removal to the nearest Government bungalow. He was, therefore, carefully carried by hammock to the English post at Debisu, a distance of 15 miles through the forest. The trying effect of this journey luckily led to no harm and was well tolerated. After being nursed for ten days in the Commissioner's house the patient had so far recovered as to be able to be brought down by easy stages to Djemma, some 40 miles further south, by the end of March. On April 3rd—i.e., nearly four weeks after his operation—he was allowed to get up, as the wound had completely healed.

A few days later the hernia showed signs of recurrence. It was, however, easily reduced and was kept in place by means of a truss, which by good chance it had been possible to obtain from the surgical stores of a French post within reach and to adjust to the required size and position. Before the Commission finally left the Gold Coast in May the satisfactory account was received that the boy was well and was still wearing the truss and that the hernia had not recurred. So happy an escape from his grave plight even the rosiest optimist would scarcely have ventured to predict; for under the conditions which had to be faced, the odds were anything but in favour of the patient's recovery.

I am, Sir, yours faithfully,

London March 8th, 1920. VIATOR MEDICUS.

"REMINISCENCES OF THREE CAMPAIGNS."

THE following correspondence has been forwarded to us for publication by Sir Launcelotte Gubbins.

[ENCLOSURE.]

Sir Alexander Ogston, K.C.V.O., &c.

DEAR SIR,—A few days back, when in the library of a London club, I took up a book entitled "Reminiscences of Three Campaigns," by Sir Alexander Ogston, K.C.V.O., &c., and glancing through it I came across at p. 71 (as well I can recollect) the following sentence: "An army medical officer in high command in General Kelly Kenny's army and who afterwards rose to the rank of Director-General, wrote, I believe, to headquarters complaining of my wearing the Queen's uniform without authorisation."

As during the South African War I was P.M.O. (to use the old title) on the staff of Sir Thomas Kelly Kenny, commanding the 6th Division, the above could only apply to me, and I would be glad to know your authority for making a statement which I most emphatically repudiate. Not having the honour of your acquaintance and not knowing you—even by sight—it was a matter of complete indifference whether you were dressed in uniform or not.

It is not always—to put it mildly—judicious to base an assertion on a mere belief, but it might interest you to know that, so far from being the hide-bound official you seek to portray, I was throughout the campaign entirely in favour, both on administrative and disciplinary grounds, of all civil surgeons employed with the army, being—in addition to wearing uniform—granted temporary commissions in the R.A.M.C., a course which was adopted with conspicuous success during the recent world-wide conflict.

Faithfully yours,

(Signed) LAUNCELOTTE GUBBINS,
Lieutenant-General (retired), and late
Director-General, A.M.S.

Belvedere Drive, Wimbledon, Surrey, March 6th, 1920.

Lieutenant-General Gubbins.

DEAR SIR,—I am favoured with your letter of the 6th instant, concerning a paragraph in my "Reminiscences." I greatly regret that the paragraph was inserted, and am sincerely sorry that it has caused you annoyance. I shall see that in future the paragraph is omitted or corrected.

Yours faithfully,

(Signed) ALEX. OGSTON.

252, Union-street, Aberdeen, March 11th, 1920.

THE SALARY OF POLICE SURGEONS AT BRISTOL.—The allowances of police surgeons for professional services for each member of the force has been increased from 7*s*. 6*d*. to 10*s*. per annum, and the salary of the chief police surgeon will in future be £200 a year instead of £150. These increases in remuneration do not appear to err on the liberal side.

Obituary.

CHARLES EDWARD LIESCHING, M.R.C.S., L.R.C.P.,

CONSULTING SURGEON, TIVERTON HOSPITAL.

Mr. C. E. Liesching died suddenly on March 4th, when apparently convalescent from an attack of influenza, at his residence at Tiverton. He was born in Ceylon 57 years ago, and was educated at Blundell's School, where he was in the cricket XI. and the football XV., and at St. George's Hospital. He qualified M.R.C.S. in 1885 and L.R.C.P. in the following year, and subsequently held the posts of ophthalmic and orthopædic assistant at St. George's Hospital, clinical assistant at the Victoria Hospital for Children, Chelsea, and house surgeon at the Stroud General Hospital. He returned to Tiverton as partner of the late Dr. W. R. Haydon, and soon acquired the respect and esteem of a large circle of friends and patients. Imbued with a deep love of his profession and a keen sense of duty, he took a great interest in his patients' welfare.

Mr. Liesching had contributed to THE LANCET, and took much interest in the advancement of medical and surgical knowledge. Preventive medicine appealed strongly to him, and as a member of the town council for over 20 years he constantly strove for the improvement of the local sanitation and water-supply. He was a member of the Education Committee and of the Joint Hospital Board for the isolation hospital, and consulting surgeon to the Tiverton Hospital. For some years he lectured in connexion with the St. John Ambulance Association, and on the outbreak of the war he took a leading part in organising a voluntary aid hospital, of which he was appointed medical officer. He was a magistrate for the borough of Tiverton. In addition to his many other duties, he devoted much time to religious activities, being honorary local treasurer for the British and Foreign Bible Society, superintendent of St. Paul's Sunday School, and a lay reader.

Mr. Liesching, in 1891, married his cousin Annie Kathleen, daughter of Surgeon-General W. Carden Roe, and leaves a widow, five sons, and five daughters, for whom much sympathy has been manifested in the district.

WILLIAM AUGUSTUS BONNEY, M.D. BRUX., F.R.C.S. EDIN.

THE death has occurred, at his house in Elm Park-gardens, of Dr. W. A. Bonney, at the advanced age of 80 years; he died in harness, for he contracted influenzal pneumonia while still in attendance upon patients.

William Bonney had a long connexion with South-West London. His grandfather, a solicitor at Brentford, was imprisoned in the Tower of London with Horne Tooke, then Vicar of Brentford, at the end of the eighteenth century on a charge of conspiracy—they being, it is alleged, the last political prisoners to be lodged in the Tower of London. His father, named Francis Burdett after the famous Liberal politician, was a doctor at Brentford, and Dr. Bonney served his original apprenticeship at the adjoining suburb of Twickenham. He joined the medical school of the Middlesex Hospital in 1863 and upon qualification was appointed resident obstetric officer to the hospital. In 1867 he returned to his native quarters, and for upwards of 60 years practised his profession at various addresses in Chelsea. He started practice in one of the charming old houses recently demolished in King's-road, opposite Paulton-square, but in 1880 he moved to Beaufort-street and in 1891 to Elm Park-gardens. He thus saw the complete transformation of Chelsea from a picturesque suburb to a modernised, though attractive, residential neighbourhood.

Dr. Bonney was an exceedingly good general practitioner—a man of strong opinions and great attainments. His resolution to remain abreast of professional knowledge is well shown in the dates at which he obtained his various qualifications. He first qualified as M.R.C.S. in 1866, but in 1880 he took the L.R.C.P. and L.M. of Edinburgh, and two years later the M.D. degree at Brussels. Finally, in 1895, when 54 years old, he became, by examination, a Fellow of the Royal College of Surgeons of Edinburgh, studying for the diploma at the Middlesex Hospital, where his son Victor, now a member of the honorary staff, was at that time a student.

Dr. Bonney married in 1870 the daughter of a neighbouring physician, Dr. Victor Poulain, and had three sons, two of whom are in the medical profession.

JAMES CHRONNELL, M.R.C.S., L.R.C.P.,

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER FOR HINDLEY URBAN DISTRICT.

THE death occurred on March 10th at Ash Cottage, Hindley, of Mr. James Chronnell, who was police surgeon for the Ince Division of the Lancashire county police and medical officer of health and school medical officer to the Hindley urban district. He had recently been appointed whole-time medical officer of health and school medical officer, and was retiring from the general practice he had held for 32 years to take up these duties. He was one of the best known practitioners in the district, and was held in high esteem alike by the public and his fellow practitioners. Behind a somewhat stern exterior, to those who knew him Mr. Chronnell was a true and generous friend and a wise counsellor. His large practice and his numerous public appointments occupied his time of recent years to the exclusion of his former athletic hobbies, and, though a keen motorist, his interests were almost entirely centred in his profession. His duties were carried out with the perfection of thoroughness. The increased strain of the war and the loss in action of his only son, Captain Hubert Chronnell, M.C., of the Loyal North Lancashire Regiment, helped in no small measure to undermine a strong constitution. Complications supervening on glycosuria a fortnight ago ended in a sudden attack of syncope. Mr. Chronnell is survived by his widow and an only daughter. The funeral took place on March 13th at Castle Hill Cemetery, and was largely attended. The gap left by the deceased is one that will be hard to fill. There remain of him a fragrant memory and a monument of work well done.

The Services.

ARMY MEDICAL SERVICE.

Major-Gen. Sir W. W. Pike is placed on retired pay.

Cols. E. H. Condon and A. G. Thompson retire on retired pay.

ROYAL ARMY MEDICAL CORPS.

Temp. Capts. J. W. C. Gunn, L. R. Broster, A. C. Bryson, N. McA. Gregg, and F. J. Fahy relinquish the acting rank of Major.

Temp. Capt. G. Marshall to be acting Major.

Capt. S. Robertson resigns his commission.

Capt. G. J. Keane retires, receiving a gratuity.

P. H. S. Smith, late Surgeon-Lieutenant, R.N., and Temp. Lieut. G. A. Fothergill to be temporary Captains.

G. R. Waller to be temporary Lieutenant.

Officers relinquishing their commissions:—G. W. Milne (granted the rank of Lieutenant-Colonel). Temporary Captains granted the rank of Major: A. C. Hancock, H. Dudley (acting Major). Temporary Captains retaining the rank of Captain: J. K. Clarke, T. W. Shaw, W. H. Swaffield, A. Leach, C. Dean, W. L. Locke, J. M. D. Scott.

SPECIAL RESERVE OF OFFICERS.

Capt. (acting Major) E. J. Bradley and Capt. W. B. Foley relinquish the acting rank of Major.

Capt. J. W. Mann relinquishes his commission and retains the rank of Captain.

Capt. D. McEachran relinquishes his commission.

Capt. A. W. Wells resigns his commission.

Capts. (acting Majors) J. St. G. Wilson and E. C. Hobbs relinquish the acting rank of Major on ceasing to be specially employed.

Capt. (acting Major) M. Coplans relinquishes the acting rank of Major on ceasing to hold the appointment of Deputy Assistant Director of Medical Services.

2nd London Sanitary Company: Capt. D. Smith is restored to the establishment.

3rd Southern General Hospital: Capt. R. E. Humphry relinquishes his commission and is granted the rank of Major.

ROYAL AIR FORCE.

Medical Branch.—Flight. Lieut. H. W. Scott to be acting Squadron Leader whilst employed as Squadron Leader.

The undermentioned are transferred to the unemployed list:—Capts. A. E. Collie, H. F. Squire, G. Dunderdale; Lieut. R. E. Burns.

Dental Branch.—Capt. A. C. S. Cottam is transferred to the unemployed list.

INDIAN MEDICAL SERVICE.

Majors to be Lieutenant-Colonels: (Bt. Lieut.-Col.) J. D. Graham, (temp. Lieut.-Col.) C. A. Sprawson, (Bt. Lieut.-Col.) M. Mackelvie, (acting Lieut.-Col.) W. Lapsley, (acting Lieut.-Col.) W. H. Cazaly, W. V. Coppinger, A. Spitteler, J. C. S. Oxley, (Bt. Lieut.-Col.) L. J. M. Deas, W. M. Houston, W. D. A. Keys, G. J. G. Young, J. Good, A. Chalmers, W. G. Hamilton, S. R. Godkin.

To be Lieutenant: (Temp. Capt.) Anil Chandra Chatterji (and retains the temporary rank of Captain).

The King has approved the grant of the temporary rank of Captain to the undermentioned: A. R. Upton, S. V. P. Pill.

The King has approved the resignation of Capt. J. J. Liston and the retirement of Lieut.-Col. W. H. Cazaly.

Medical News.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At the examination just concluded for the Single Licence Diploma of the College Mr. Susil Kumar Mukhopadhaya, L.M.S. Calcutta, passed the examination and was granted the diploma L.R.C.S. Edin.

At the recent Dental Examinations the following candidates passed the Final Examination and were granted the diploma L.D.S. R.C.S. Edin.:—

Ernest Joseph Millhouse, South Australia; Frederick Duncan Stephenson, Robert Haddow Mitchell, and Frederick James Duncan Cass, Edinburgh; Henry Augustus Taylor, Leith; George Thomas Paterson, Portobello; Alfred Charles Trotter, Simla, India; Arthur Brown, South Shields; and Joseph Nixon, Whitehaven.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—The annual general meeting will be held to-day, Friday, March 19th, at 3 o'clock, at the Mansion House, when the Lord Mayor will preside, and the speakers will include Lady Barrett, M.D., Miss Lilian Braithwaite, and the Rev. H. R. L. Sheppard.

LONDON TEMPERANCE HOSPITAL.—The annual meeting will be held in the out-patient hall on Friday, March 26th, at 5 P.M., the Marquis of Lincolnshire in the chair, when addresses will be delivered by Sir Alfred Pearce Gould, Dr. J. Porter Parkinson, Mr. Arthur Evans, and others.

MIDDLESEX HOSPITAL MEDICAL SOCIETY.—The annual special meeting of this society will be held at the Middlesex Hospital on Friday, March 26th, at 8.30 P.M., when Sir Humphry Rolleston will deliver an address entitled "John Smith's Sacred Anatomy." Demonstrations will be given on the following subjects: Electro-therapeutics, electro-cardiography, and certain bacteriological subjects.

MEDICAL SOCIETY OF LONDON.—The 147th anniversary dinner, held at the Wharncliffe Rooms on Wednesday, March 17th, was not made the occasion of any important pronouncement of achievement or policy, but was entirely given up to good fellowship. Mr. V. Warren Low presided, and the guests included Sir George Makins, Sir Robert Hill, Sir John Goodwin, Sir Archibald Garrod, and Sir Humphry Rolleston. In the course of the evening the Fothergillian gold medal of the society was handed to Dr. Henry Head.

NO. 53 GENERAL HOSPITAL (B.E.F.).—The first reunion dinner of officers and nursing staff will take place on Thursday next, March 25th, at the Hotel Great Central, at 7.30 for 7.45 P.M. Those who wish to be present should communicate at once with: (officers) Lieutenant-Colonel E. M. Callender, C.B.E., 73, Sussex Gardens, London, W. 2.; (nurses) Miss M. S. Riddell, Principal Matron, T.F.N.S., 80, Pall Mall, S.W. 1.

CENTENARIANS.—The deaths of Miss Margaret Davison at Tunbridge Wells, aged 102, and of Miss Elizabeth McCusker, of Greenock, in her 108th year, have recently been reported.—Mr. Robert Lanyon, of Gorran, Cornwall, who celebrated the 100th anniversary of his birthday in November last, died on March 2nd.—Mrs. Nash, of Guildford, celebrated the 100th anniversary of her birthday on March 10th.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—The Council of the Royal Society of Medicine agreed at its meeting on March 16th to officially appoint its representatives to the Federation.

ROYAL INSTITUTION.—Among the lectures to be given at the institution after Easter are two by Major G. W. C. Kaye, on Recent Advances in X Ray Work, and four by Professor Arthur Keith on British Ethnology. The Friday evening meetings will be resumed on April 16th, when Professor J. A. McClelland will deliver a discourse on Ions and Nuclei.

THE LATE DR. S. FALKNER.—Dr. Sandbrook Falkner, who died recently at St. George's Hospital, aged 45, from septicæmia following a scratch on his thumb during an operation, was a well-known divisional surgeon to the Metropolitan Police in Fulham. He studied medicine at the London Hospital and obtained the qualification of the Conjoint Board in 1910. Dr. Falkner was radiologist to the Fulham School Clinic.

AT the last meeting of the Falmouth Borough Council, the resignation of Dr. A. Gregor, the medical officer of health, was accepted with much regret, and members of the Council stated they wished publicly to thank Dr. Gregor for his splendid services. The mayor added that they were in communication with the Ministry of Health in the hope of arranging to show their appreciation of Dr. Gregor's work in a tangible form.

Mr. Douglas H. W. Robson-Burrows, of Summerfield, Bournemouth, late a director of Messrs. Oppenheimer, Son and Co., was governor of the Royal Victoria and West Hants Hospital. He left an estate of the value of £18,544, the residue of which, exceeding £10,000, is bequeathed to the hospital.

PROVISIONAL ARTIFICIAL LEGS.—The Ministry of Pensions supply soldiers and pensioners who have suffered amputation of the leg with a provisional limb to supplement the permanent mechanical limbs that have been and are being supplied. The value of the provisional limb lies in its acting as a kind of "slipper" and as a reserve in case of accident to the mechanical limb. The Ministry is now announcing that if a pensioner has not received a second mechanical limb he is entitled to apply to his local War Pensions Committee for a provisional limb, when arrangements will be made with the nearest limb-fitting hospital, working in connexion with a Red Cross Provisional Limbs Depôt.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee, held on March 9th, 23 cases were considered, and £224 voted to 21 of the applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 50, of M.R.C.S. Eng. who practised at Ryde and died in 1915. Her only income is £40 as a daily governess, and £10 from her sister. She has had a mental breakdown, and needs an entire change. She pays £9 2*s*. a year for one unfurnished room. Voted £5.—Daughter, aged 64, of F.R.C.S. Eng. who practised at Great Dunmow and died in 1887. Only income 10*s*. a week by gardening. Lives with an old aunt who provides for her. Asks for help owing to age, ill-health, and the high cost of living. Voted £12 in 12 instalments.—Widow, aged 40, of M.B. Lond. who practised at St. Helens and died in 1918. Was left unprovided for with three children, ages 5½, 4, and 2. Income £60 a year from dividends, and £65 from letting rooms. Pays £39 for rent and rates. Relieved twice, £20. Voted £16 in two instalments.—L.R.C.P. & S. Edin., aged 73, who practised at Dovercourt. He suffers from ill-health, and his practice has fallen off since the war. Has lost an annuity of £108 owing to the war. Receives about £103 from practice, and £10 an annuity. Has one daughter who helps at home, as his wife has very bad health. Rent £35. Relieved once, £10. Voted £10.—M.R.C.S. Eng., aged 53, who practised at Liverpool and abroad. Suffers from ill-health due to foreign climate, and has had to give up practice. Lives with his aunt. Receives £24 a year from friends, and earns about 6*s*. a week by his own efforts. Rent and rates £7 4*s*. 10*d*. Relieved seven times, £60. Voted £10 in two instalments.—Widow, aged 49, of M.B. Glasg. who practised in Nottingham and died in 1914. Takes in paying guests, by which she makes about £100 a year. Has two daughters, both at boarding school. Income spent in repairing and redecorating house, previous to letting it. Rent and rates £57. Relieved twice, £22. Voted £12.—Widow, aged 66, of M.D. Edin. who practised at Edinburgh and died in 1909. Was left with four children, one now married. Children pay £78, and she receives £12 from another charity. Pays £1 a week for lodgings, and 2*s*. 6*d*. for storing furniture. Relieved 11 times, £116. Voted £12 in 12 instalments.—Daughter, aged 56, of M.R.C.S. Eng. who practised in London and died in 1895. Was left entirely without means. She receives 17*s*. a year from a small sum invested and £21 from another charity. Pays £1 1*s*. a week for board and lodging. Suffers from ill-health and is unable to work. Relieved seven times, £87. Voted £12 in 12 instalments.—Daughter, aged 58, of M.R.C.S. Eng. who practised in London and died in 1880. She lives with widowed sister and her only income is £60 from other charities. Has very bad health. Relieved 10 times, £108. Voted £12 in 12 instalments.

Subscriptions should be sent to the honorary treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

UNIVERSITY OF BRISTOL.—The Victoria Rooms, lifton, will be acquired by the University, and after ecessary alterations be used [illegible] a common room or social lub for the undergraduates.

THE Wellcome Historical Medical Museum, 4A, Wigmore-street, Cavendish-square, W., will be closed or cleaning and re-decoration from April 1st to 30th, nclusive.

DEVON MENTAL HOSPITAL.—The Mental Hospital ommittee of the Devon County Council has decided to rect 24 houses, in blocks of six, for the use of asylum ttendants. The cost of the scheme is estimated at about 14,855.

MAUDSLEY NEUROLOGICAL HOSPITAL: COURSE IN SYCHOLOGICAL MEDICINE.—The lectures for Part I. of the iploma of Psychological Medicine will be given on Monday, Wednesday, and Friday afternoons, from 2.30–5.30 P.M., eginning on Wednesday, March 24th. The course includes 2 lectures on the anatomy of the nervous system by Sir rederick Mott, with practical instruction and demonstraons (eight sessions of two hours each); 12 lectures on the hysiology of the nervous system by Dr. F. L. Golla, with ractical physiology (ten sessions); 10 lectures on psychology y Dr. J. P. Lowson, with practical work and demonstrations ight sessions). The fees for the whole course of Part I. and art II. are £15 15s., for either part separately £10 10s. rrangements for Part II. will be announced later. Applicaions for admission should be addressed to the Asylums fficer, 13, Arundel-street, London, W.C. 2.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.—At a meeting of the Scottish Central Midwives Board, held ecently in Edinburgh, Sir J. Halliday Croom in the chair, he following penal cases were under consideration :—

(1) Failure to notify ophthalmia neonatorum, whereby the child's es were permanently impaired, and other breaches of the rules. vidence that midwife had conducted cases for years without any ntoward circumstance arising. Suspended from practice as a idwife for three months; the local supervising authority to report n her ability to take and record temperatures and pulses.

(2) Failure to notify still-birth and other breaches of the rules. everely reprimanded.

(3) Convicted in the Police-court, Perth, of keeping an improper ouse, when she was fined 40s. Name removed from the roll.

(4) Having been in contact with a patient suffering from puerperal ver, failed to make the required notifications and to take the ecessary precautions whereby other patients were affected. ame removed from the roll.

(5) Failure to notify ophthalmia neonatorum, and other breaches f the rules. No permanent disability to the eyes of the child. hairman intimated that before proceeding with the extreme enalty of removing the name from the roll the nurse would be iven an opportunity of proving amendment. Local supervising uthority requested for a report at the end of three months.

Two other names were removed from the roll, one of a ertified midwife who had been sentenced to six months' nprisonment for theft and fraud, the other of a certified idwife sentenced to 18 months' imprisonment for using nstruments with intent to procure abortion.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF EDICINE FOR WOMEN.—Over 300 past and present students nd friends of this school assembled on March 12th at the rst reunion dinner held since before the war. In the bsence of Miss Louisa Aldrich-Blake, the Dean, through a roken kneecap, Dr. May Thorne presided, and in an dmirable speech describing the development of the school nd hospital since the last reunion, outlined plans, includng the formation of at least one clinical unit, for their rther extension. She then gave a brief summary of the ork done and the distinctions gained by members of the chool in the various fields of the war. Finally, Dr. Thorne ommended the appeal for funds—circulated as a leaflet—to he attention of the guests, and expressing her confidence of generous response, proposed the toast of the Royal Free ospital and the London School of Medicine for Women. n replying for the hospital, Dr. J. W. Carr spoke of the aried interests in the life of a modern student, and eferred to one who was recently discovered simulaneously nursing her baby, smoking a cigarette, and eading a book on surgery. Miss Sybil Widdows, B.Sc., ecturer on inorganic chemistry at the school, responded or the London School of Medicine for Women. In a peech that aroused keen interest, she gave an account f some of the work of the students and of their oyalty to the hospital. The guests present included ir Cooper Perry, Sir Thomas Barlow, and Sir Walter letcher, who responded on their behalf to the toast roposed by Lady Barrett. The health of Dr. Thorne, roposed by the Right Hon. F. D. Acland, M.P., chairman f the school, was also drunk with enthusiasm. The only rawback to an otherwise successful evening was the length f the formal proceedings which gave little time for the informal reunion of old friends, to which many past students had looked forward. The scheme outlined in the leaflet distributed to all present is the enlargement of the Royal Free Hospital to hold 450 beds. Of these 230 will be entirely free for poor patients and 220 will be allocated to persons of moderate means who can pay 3 guineas a week towards the expenses of their maintenance. The amount of money required is estimated at £500,000, to be distributed as follows: Hospital extension, £300,000; nurses' and service quarters, £50,000; equipment and maintenance charges, £100,000; school extension, £50,000. Any further information will be given by the honorary secretary, Dr. May Thorne, 8, Hunter-street, London, W.C. 1, while donations should be sent to the honorary treasurer of the appeal, Sir Francis Layland-Barratt, Bart., Royal Free Hospital, Gray's Inn-road, London, W.C. 1.

PSYCHO-NEUROLOGICAL SOCIETY.—At a committee meeting of the Lancaster Gate Medical Society (for the study of psychotherapy), held on March 1st, it was resolved that in future the society be known as the Psycho-Neurological Society, and that its object be "the study of psychological and neurological medicine." The officers for the year are: President, Dr. David Forsyth. Vice-President, Dr. W. A. Brend; honorary secretary, Dr. C. Worster-Drought; honorary treasurer, Dr. P. Bousfield. On Feb. 22nd a paper was read by Dr. Henry Head entitled "The Elements of the Psychoneuroses." An interesting discussion followed in which Drs. Forsyth, Brend, Worster. Drought, M. Culpin, R. Travers Smith, H. Linnell, and G. De Vine took part. On March 15th Dr. Travers Smith read [illegible] paper entitled "The Simulation of V.D.H." In the discussion that followed most of the speakers deplored the fact that the psychological basis of cases of "D.A.H." is so frequently overlooked.

URBAN VITAL STATISTICS.

(Week ended March 13th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 15·6, 16·4, and 16·9 in the three preceding weeks, further rose to 17·1 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 17·2, or 0·2 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 6·5 in Eastbourne, 7·2 in Cambridge, and 7·7 in Hornsey to 26·2 in Middlesbrough, 26·7 in South Shields, and 29 3 in Barnsley. The principal epidemic diseases caused 467 deaths, which corresponded to an annual rate of 1·4 per 1000, and comprised 199 from measles, 108 from whooping-cough, 79 from diphtheria, 49 from infantile diarrhœa, 25 from scarlet fever, 5 from enteric fever, and 2 from small-pox. Measles caused a death-rate of 2·6 in Lincoln, Grimsby and St. Helens, 3·0 in Barnsley, 3·2 in Wakefield, and 5·2 in Gloucester; whooping-cough of 5·2 in Gloucester; and diphtheria of 3·1 in Gloucester. The two fatal cases of small-pox belonged to the metropolitan borough of Poplar. The deaths from influenza, which had increased from 66 to 196 in the six preceding weeks, further rose to 230, and included 57 in London, 32 in Birmingham, 17 in Liverpool, 11 in Plymouth, and 7 each in Dudley, Manchester, and Leeds. There were 2182 cases of scarlet fever, 2045 of diphtheria, and 7 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2255, 2006, and 7 respectively at the end of the previous week. The causes of 43 deaths in the 96 towns were uncertified, of which 12 were registered in Birmingham, 4 in Liverpool, and 3 each in London and South Shields.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 15·7 in each of the two preceding weeks, rose to 16·0 per 1000. The 317 deaths in Glasgow corresponded to [illegible] annual rate of 14·9 per 1000, and included 7 each from measles and influenza, 4 from diphtheria, 2 from whooping-cough, and 1 each from small-pox, scarlet fever, and infantile diarrhœa. The 114 deaths in Edinburgh were equal to a rate of 17·4 per 1000, and included 5 from measles, 2 each from diphtheria and influenza, and 1 each from scarlet fever and infantile diarrhœa.

Irish Towns.—The 159 deaths in Dublin corresponded to an annual rate of 20 0, or 0·7 per 1000 below that recorded in the previous week, and included 6 from whooping-cough and 3 each from measles and infantile diarrhœa. The 225 deaths in Belfast were equal to a rate of 28·4 per 1000, and included 23 from influenza, 7 from measles, 4 from scarlet fever, 3 from whooping-cough, 2 each from enteric fever and diphtheria, and 1 from infantile diarrhœa.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, March 10th.

Treatment Centres for Venereal Disease.

Mr. John Davison asked the Minister of Health whether he had arranged for the keeping of records regarding the treatment centres for venereal diseases established partly or wholly at the public expense; whether he could state the number of cases that had been dealt with for the first time at such centres; and what had been the expenditure in connexion with such centres from national and local funds respectively for each year since their establishment.—Dr. Addison replied: The answer to the first part of the question is in the affirmative. The number of cases dealt with for the first time at these centres between Jan. 1st, 1917, when the first treatment centres were opened, and Dec. 31st, 1919, is approximately 175,000. The approximate expenditure of local authorities on their schemes for the diagnosis and treatment of venereal diseases during the years ended March 31st, 1917, 1918, and 1919 amounted to £18,000, £116,000, and £216,000 respectively. The estimated expenditure during the current financial year is £314,000. Of this expenditure 75 per cent. is borne by national funds and 25 per cent. by local funds.

Institutional Provision for Tuberculous Persons.

Lieutenant-Colonel Fremantle asked the Minister of Health whether the legislation necessary before he could decide the future utilisation of Poor-law infirmaries was to be expected this session; and, if not, whether he would give such definite advice to boards of guardians as would enable them to make the institutional provision urgently required for tuberculous persons without incurring expenditure on accommodation which might be unsuitable for its ultimate purpose.—Dr. Addison replied: I am not yet in a position to make any statement in regard to the first part of the question. As regards the latter part of the question, it is not the policy of the Government to encourage boards of guardians to make additional provision for tuberculous persons. I am pressing upon the public health authorities the need for providing further institutional accommodation for these cases with the aid of substantial financial assistance from the Exchequer.

Lieutenant-Colonel Fremantle: Does not that mean a large amount of institutional provision that may be superfluous when there are Poor-law institutions available for the purpose and suitable?—Dr. Addison: I do not think it does. As a matter of fact, we are several thousand beds short at the present time.

Arsenical Treatment of Syphilis.

Mr. Tyson Wilson asked the Secretary for War whether any inquests were held in respect of any of the deaths of soldiers after arsenical treatment for syphilis, referred to in the paper read by Brevet-Colonel L. W. Harrison at the meeting of the British Medical Association in April last; whether the deaths mentioned in that paper comprised all the deaths of that description occurring in the British Army during the years of the war; and if not, would he supply a complete table of figures showing how many such deaths occurred at each of the Colonial and Imperial venereal hospitals in this country and abroad.—Sir A. Williamson: I am obtaining information regarding the first part of the honourable Member's question. It is not possible to give a complete answer to the remainder of the question, as the records of many of the hospitals concerned have been, or are being, forwarded to the Medical Research Committee for compiling the medical history and medical statistics of the war.

Thursday, March 11th.

Pensions and Gratuities in the Massage Service.

Major Hills asked the Pensions Minister whether his attention had been directed to the fact that members of the Massage Service received no bonus, gratuity, or pension; whether members of this service had worked all through the war; and whether he would secure for them either a pension or a gratuity or both.—Sir L. Worthington-Evans replied: The Ministry of Pensions Massage Service has in the main been recruited from the Military Massage Service, and the personnel have worked for varying periods during the war. In common with the rest of the temporary staff of the Ministry, the Massage Service are not entitled to bonus, gratuity, or pension, and there would appear to be no ground for their being accorded exceptional treatment in this respect.

Medical Boards and Disability Pensions.

Captain Loseby asked the Pensions Minister if he was aware that medical boards still frequently refused to inform soldiers immediately after examination of the degree of disability at which they had been assessed; and if he would consider the advisability of issuing emphatic instructions upon this subject.—Sir L. Worthington-Evans replied: I am sending the honourable and gallant Member a copy of an Office Instruction, issued in December of last year, from which he will see that explicit directions have been issued to medical boards in this matter. I shall be glad to have particulars of any cases where these directions are not being observed.

Captain Loseby: Is the right honourable gentleman aware that this omission is particularly striking in the case of disabled soldiers wounded prior to 1914 who are being re-assessed?—Sir L. Worthington-Evans: I have not had my attention called to any differentiation between pre-1914 and post-1914 men, but I will see if there is any such differentiation. There is no instruction.

Small-pox in Poplar.

Mr. William Thorne asked the President of the Board of Education whether he was aware that at least 300 school children had been taken to the Poplar cleansing station at Bromley-by-Bow since the outbreak of small-pox in that district on Feb. 14th; whether the door of this cleansing station opened directly on to the infected side of the disinfecting station; whether the children's clothing was taken through this door; whether contacts since removed to hospital suffering from small-pox were brought to this station; whether a man working at the station had been removed suffering from small-pox; what action he proposed to take should any of the children sent to this station for cleansing purposes develop small-pox; whether he would see that the parents of such children were fully compensated; and whether he would arrange that any children needing cleansing should be sent to other stations while small-pox infection was likely to prevail near the station at Bromley-by-Bow.—Dr. Addison (Minister of Health) replied: The answer to the first part of the question is in the affirmative. As regards the remainder of the question, I am advised that the facts are as follows: The cleansing station is within the same ground as the disinfecting station, but the children who are taken to the cleansing station do not enter or leave the cleansing station by the door opening into the large yard, which contains also the entrance to the infected side of the disinfecting station. The children's clothing is, of course, taken through the door to the disinfecting station. The contacts with cases of small-pox are brought for necessary disinfection to a shelter which in within the same ground as the cleansing station, but is situated at some considerable distance from that station. The man referred to in the question was the driver of the disinfecting van, whose duties took him to the home of a person who had been removed suffering from small-pox. The man was aware of that fact, but nevertheless he refused to be vaccinated. I have no authority to direct the payment of any compensation to the parents of children who may contract small-pox, nor do I consider it necessary at present to close the station to children. But several cases of small-pox have recently occurred in Poplar, and it is obviously the duty of parents to see that their children are protected by vaccination.

Veterinary Surgeons Bill.

Sir Watson Cheyne moved the second reading of the Veterinary Surgeons Act (1881) Amendment Bill. He said that it was a very short Bill, produced on behalf of the Royal College of Veterinary Surgeons, the only College of its kind in the kingdom. There was an average of 70 or 80 admissions to the College every year, and the income was not anything like sufficient to pay expenses. The College was only able to carry on by voluntary contributions. There were 2300 members on the register, and 1100 of these gave one guinea a year. The proposal of the Bill was that there should not be merely an admission fee, but also an annual fee of one guinea. The Bill would also prevent unqualified men practising under the name of a veterinary dispensary or hospital.—Brigadier-General Colvin moved the rejection of the Bill. The unregistered practitioners, he said, had very large practices throughout the country, and without their assistance the farmers and other owners of stock could not possibly get on. —Mr. Jodrell seconded the rejection of the Bill. It was quite true, he said, that the measure in itself was reasonable and logical and had a great deal to commend it to everyone interested in science and in the scientific advancement of veterinary work throughout the country. Still, at the back of the Bill there was a suggestion of compulsion being put upon a large class of men to join in the working of a College which they were incapable of doing for want of previous education.—Sir H. Craik said there was no desire to prosecute unqualified men or those who occasionally employed their assistance; but it was desired that ill-equipped practitioners should be stopped from acting independently.—On a division the second reading of the Bill was agreed to by 106 votes to 51.

Friday, March 12th.

Aid for the Blind.

Mr. Tillett, in moving the second reading of the Blind (Education, Employment, and Maintenance) Bill, said that the object of the measure was to provide for the technical education of the blind by the establishment and equipment of technical schools where necessary, or by contributions to existing schools and institutions; for the employment of the blind by the establishment and equipment of workshops where necessary, or by contributions to existing institutions providing work for the blind, and for grants to augment the wages earned by persons so employed; for the expenses of the blind in institutions and hostels while under technical instruction, for their employment and maintenance away from workshops, and for the maintenance of blind persons incapacitated from earning a livelihood. There were in the United Kingdom some 30,000 dependent blind persons, of whom 10,000 were supported by Poor-law authorities, 7000 were more or less industrially employed, and 2000 were directly employed industrially. Their normal efficiency was between 35 and 50 per cent. of the average. Forty per cent. of blindness occurred after the age of 35. If the report on the C 3 nation were analysed it would show that blindness and defective sight were a great danger to the nation. This Bill would deal with the preventive, curative, and remedial sides of the question. The report of the Commission on Venereal Disease showed that we had a very serious situation to face. Twenty-five per cent. of blindness was due to gonorrhœa in the mother. He thanked the Government, the Ministry of Health, and the voluntary institutions for all they had done. Yet, looking back, he thought, as a race, we had done very little for the blind.

Dr. ADDISON, speaking for the Government, asked the House to deal with this question as a whole. They must not only deal with effects, but also with causes. He found that a very large number of the cases in the London County Council blind schools were due to preventable conditions—he referred to venereal disease in one or other of its forms. It was no exaggeration to say that while one-fifth of the blind were blind within six months of birth nearly all those cases could have been prevented. He was not satisfied that they had yet covered the ground properly in regard to the prevention of blindness. He would therefore adopt the suggestion that there should be a more methodical and comprehensive inquiry of a scientific character into the causes which led to blindness. The Board of Education was now pressing local authorities to extend the facilities for training by giving assistance to private and voluntary organisations. Parliament must take care that the interests of the blind and the sympathies of the public were not exploited by those who were not worthy of support. The Government would therefore propose to require the registration of agencies seeking support of a voluntary character for the blind. The Government were prepared to support proposals enabling county councils, borough councils, and possibly other bodies to contribute towards the provision and maintenance of workshops, hostels, and homes for the blind. It was clear to him, after careful inquiry, that blind persons after the age of 50 could not be taught anything, and in respect to that class the Government proposed to adopt a special class of relief, and to use for it the same machinery as in regard to Old-age Pensions. Between the ages of 50 and 70 blind persons would receive, subject to the same disqualifications as to income and so forth, the same benefits and weekly allowances as old-age pensioners. That would really meet the cases of 46 per cent. of the blind who were indigent and too old to be taught. He suggested that the House should give the Bill a second reading, and that he should consult those who were specially interested in the subject so that the Bill might either be remodelled or another introduced to give effect to the Government proposals.—The second reading of the Bill was carried unanimously.

MONDAY, MARCH 15TH.

Deficiency of Officers in the Indian Medical Service.

Colonel YATE asked the Secretary for India if he would state what was the present deficiency of officers in the Indian Medical Service; and how many candidates had been forthcoming in the past year.—Mr. FISHER (Minister of Education) replied: In a report received from the Government of India in July last they estimated that 166 officers were required to bring the Indian Medical Service up to the strength required by present conditions.

Sanatoriums for Uncertifiable Mental Cases.

Mr. RENDALL asked the Minister of Health what steps he intended to take in regard to the provision of sanatoriums for uncertifiable mental cases; and whether for the encouragement of voluntary patients such homes should be kept on a hospital footing, that was free from detention and wholly unconnected with lunacy administration, so as to prevent their being regarded as half-way houses to asylums.—Dr. ADDISON replied: Any scheme on the lines of my honourable friend's suggestion, with which I am entirely in sympathy, would require legislation. The question is under consideration, but I am not yet in a position to state when the necessary legislation will be introduced.

Illness on the s.s. "Dufferin."

Major MACKENZIE WOOD asked the President of the Board of Trade whether the steamship *Dufferin*, which sailed recently from Southampton to Bombay, was in an insanitary and crowded condition; whether a serious outbreak of illness, affecting 500 persons, occurred on board; and what action he proposed to take in the matter.—Mr. FISHER replied: The answer to the first part of the question is in the negative. The ship was thoroughly disinfected by the Clayton process before sailing, and the passengers were berthed on the lines adopted on passenger steamers sailing to India. In view of the shortage it is not possible to give passengers as much space as in normal conditions. I understand that a certain amount of sickness occurred during the latter part of the voyage. There is no reason for thinking that the outbreak was serious, but inquiry will be made of the Government of India.

Rabies and the Muzzling Order.

Captain TUDOR-REES asked the Parliamentary Secretary to the Ministry of Agriculture whether there were any cases of rabies now in the country; what counties were still subject to the Muzzling Order; and when he expected to be able to cancel that Order.—Sir A. BOSCAWEN replied: The last case of rabies occurred in Surrey on Feb. 18th. The Muzzling Orders are at present in force in six different parts of the country. Owing to the abnormally long incubation period which sometimes occurs in rabies it is not considered safe to free a muzzling area within a period of six to eight months from the date of the confirmation of the last case.

Tuberculosis Order, 1913.

Lieutenant-Colonel FREMANTLE asked the Parliamentary Secretary to the Ministry of Agriculture if he would state on what date the Tuberculosis Order of 1913 would come into force; whether whole-time veterinary surgeons were to be appointed to carry on the required inspections; and whether he was acting in close coöperation with the Ministry of Health in the serious intention of reducing the prevalence of tuberculosis, so far as might be possible by Government measures.—Sir A. BOSCAWEN replied: It is anticipated that the Tuberculosis Order, either in its present form or slightly amended, will come into operation at the same time as the Milk and Dairies Act. The question of employing whole-time veterinary surgeons is under consideration, but the matter is one which presents serious difficulties. The Ministries of Health and Agriculture are acting in close coöperation in this matter, and the possibility of introducing a system whereby herds may be guaranteed free from tuberculosis is under consideration by my department.

Compensation for Small-pox.

Mr. JOHN JONES asked the Minister of Health whether he was aware that there had been an outbreak of small-pox in the borough of Poplar and in other parts of East London; and whether, in order to assist in preventing the spread of such disease, he would secure the amendment of the Workmen's Compensation Act or at once introduce legislation to enable a person contracting an infectious or contagious disease through the neglect of any individual, body of persons, or Government department to obtain compensation on similar lines to that which enabled a workman to receive compensation for contracting a disease in the course of his employment.—Dr. ADDISON replied: The answer to the first part of the question is in the affirmative. All practical steps are being taken to prevent the spread of the disease, but I do not see how the course suggested by the honourable Member would assist in that direction, and I could not undertake to introduce legislation on the lines suggested by the honourable Member.

TUESDAY, MARCH 16TH.

Medical Officers in Mesopotamia.

Sir WATSON CHEYNE asked the Secretary for War if he had been able to make any further arrangements to relieve the medical officers of the Royal Army Medical Corps in Mesopotamia (Special Reserve and Territorial Force) who had been there for some years; if he had satisfied himself that all these officers were required; if he was aware that at one centre, where five medical officers and five subordinates were stationed, it was stated that the medical work of each officer during the last six months had averaged ten minutes per day, and that for the last seven weeks prior to Jan. 24th they had not received a single patient; and whether, considering the great injury to their health and their future prospects resulting from their prolonged residence in Mesopotamia, he would use every endeavour to secure their transfer elsewhere.—Mr. CHURCHILL replied: Every endeavour continues to be made to relieve medical officers of the Special Reserve and Territorial Force serving in Mesopotamia who, on account of age, length of service in the East, and personal hardship, are considered by the General Officer Commanding to be eligible for release. The establishments are being reduced to the greatest possible extent, having regard to the care of the sick and the protection of the garrison; and regular Royal Army Medical Corps officers are being sent out as far as the available resources and the heavy demands to be met elsewhere permit. I am not aware of the particular cases mentioned, but if details are supplied I will obtain a full report. At the same time, however, I would point out that in Mesopotamia and Persia isolated bodies of troops are stationed, and these require to be provided with medical personnel, as the distances preclude the despatch of medical officers at short notice should their services at any time be urgently required.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ABRAHAMS, A., M.D. Camb., M.R.C.P. Lond., has been appointed Assistant Physician to Westminster Hospital.

FOURACRE, S. F., M.B., B.S. Lond., Honorary Anæsthetist to Charing Cross Hospital and to the National Dental Hospital.

HEATH, F. H. R., L.R.C.P., M.R.C.S.. Honorary Radiologist to the Dorset County Hospital, Dorchester.

HIGGINS, T. TWISTINGTON, F.R.C.S., Surgeon (with charge of Outpatients) at the Great Northern Central Hospital, Holloway.

KRAUSE, R. A., M.D., Ch.B. Edin., Chief School Medical Officer for the County of Fife.

RAFFAN, J., M.D. Aberd., F.R.C.S. Edin., Honorary Surgeon to the Huddersfield Royal Infirmary.

SMITH, H. GORDON, M.B., B.S. Lond., D.P.H. Camb., Medical Officer of Health to the Borough of Shrewsbury.

STEWART, P., M.B., C.M. Glasg., Certifying Surgeon under the Factory and Workshop Acts for Kirkliston.

SUNDELL, C. E., M.D. Lond., M.R.C.P., Physician in charge of the Children's Department at the Prince of Wales's General Hospital, London, N.

Vacancies.

For further information refer to the advertisement columns.

Ayr County Hospital.—Res. H.S. £120.

Barnsley, Beckett Hospital.—Jun. H.S. £150.

Battersea General Hospital, Battersea Park, S.W.—Res. M.O. £250.

Belgrave Hospital for Children, Clapham-road, S.W.—H.P. and H.S. £100 and £75 respectively.

Birkenhead Borough Hospital.—Sen. and Jun. H.S.'s. £200 and £170.

Birmingham, City Sanatorium, Yardley-road, Small Heath.—Third Asst. Res. M.O. £350.

Birmingham General Hospital.—H.S. £100.

Blackburn County Borough.—M.O.H. £1000.

Bradford Children's Hospital.—H.S. £180.

Bradford City.—Medical Woman for Ante-natal Work. £500.

Bradford Royal Infirmary.—Two H.S.'s. £200 each.

Brentwood Mental Hospital.—Med. Supt. £1000.

Brighton County Borough Sanatorium.—Res. M.O. £350.

British Guiana.—Asst. M.O. £400.

Burnley, Victoria Hospital—H.S. £250.

Cancer Hospital, Fulham-road, S.W.—Hon. Dent. S. 25 gs. Also Two H.S.'s. £150 each.

Cardiff, King Edward VII. Welsh National Memorial Association—Tuberc. P. £600.

Carlisle City.—Female Asst. M.O. £500.

Central London Ophthalmic Hospital, Judd-street, W.C.—H.S. £50.

Chelmsford, Administrative County of Essex.—Tuberc. O. £500.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Tuberc. O. £600.

Denbigh, North Wales Sanatorium,—Asst. Res. M.O. £400.

Derby, Derbyshire Royal Infirmary.—H.S. £200. Also Oph. H.S. £200.

Derbyshire Education Committee.—Sch. Dentist. £450.

Dorchester, Dorset County Council Education Committee.—School Dentists. £400.

Dover, Royal Victoria Hospital.—H.S. £180.

Eastbourne, East Sussex County Mental Hospital.—Locum Tenens Asst. M.O. 7 guineas a week.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Cas. O. £120. Also H.S. £125.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female Clin. Assts.

Evelina Hospital for Children, Southwark, S.E.—H.S. £160.

Exeter City.—Asst. M.O.H. and Asst. Sch. M.O. £500.

Glasgow Western Infirmary.—Lecturer on Electrical Diagnosis and Therapeutics.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P and Asst. H.S. £175 and £150 respectively.

Gravesend Hospital.—H.S. £200.

Great Northern Central Hospital, Holloway, N.—H.P. £150.

Greenwich, Metropolitan Borough.—Asst. M.O.H. and M.O. for Tuberculosis Dispensary. £700.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—Cas. M.O. £150. Also Hon. Dent. S.

Hospital for Sick Children, Great Ormond-street, London, W.C.—Res. Med. Supt. £200. Also Asst. Cas. M.O., H.P., and H.S. £50 each.

Hospital for Women, Soho-square, W.—Res. M.O. £100.

Leamington, Warwickshire and Coventry Joint Committee for Tuberculosis.—Asst. Tuberc. O. £500.

Leeds Public Dispensary.—Res. M.O. £200.

Leeds Tuberculosis Hospital, Killingbeck.—Med. Supt. £500.

Liverpool, City Infectious Hospitals.—Asst. Res. M.O. £250.

Liverpool Education Committee.—Two Asst. Sch. M.O.'s. £350.

Liverpool, Stanley Hospital.—Two H.S.'s. £150.

Liverpool University, Faculty of Medicine.—Lecturer in Histolog and Assoc. Prof. in Cytology.

Liverpool, Walton Institution, Rice-lane.—Asst. Res. M.O. £280+£7

Loughborough and District General Hospital and Dispensary.—Res. H.S. £200.

Macclesfield County Asylum.—Asst. M.O. £350.

Macclesfield General Infirmary. Res. H.S. £200.

Manchester Children's Hospital, Pendlebury, near Manchester.—Res. M.O. £150.

Manchester Northern Hospital for Women and Children, Park place, Cheetham Hill-road.—Hon. P.

Middlesbrough, North Ormesby Hospital.—Asst. H.S. £175.

Ministry of Health, Whitehall, S.W.—M.O.'s. £1000.

Monmouthshire County Council.—Pathol. and Bacteriol. £750.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Out-patient M.O. £90.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—H.P. £150. Also Hon. Gynæcologist.

Newark Hospital and Dispensary.—Res. H.S. £200.

Newcastle-upon-Tyne, Durham University College of Medicine.—Curator of the Museum. £250.

Oldham County Borough.—Asst. M.O. £500.

Perth Royal Infirmary.—H.S. 6 guineas per week.

Peterborough Infirmary.—Hon. P., Hon. Asst. P., and Hon. Asst. S.

Plymouth, South Devon and East Cornwall Hospital.—H.S. £200.

Prince of Wales's General Hospital, Tottenham, N.—H.P. and H.S. £200 each. Also Jun. H.P. and Jun. H.S. £120 each.

Queen Mary's Hospital for East End, Stratford, E.—H.P.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.P. £100.

Reading, Royal Berkshire Hospital.—H.P. and Second H.S. £20 each.

Redhill, Surrey, Royal Earlswood Institution.—Asst. M.O. £400.

Royal Dental Hospital of London, Leicester-square, W.—Asst. Dent. S.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. £100.

Royal Institute of Public Health, 37, Russell-square, W.C.—Senior Demonstrator of Bacteriology.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—H.S. £200.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Asst. H.S.

St. Mary's Hospital for Women and Children, Plaistow, E.—S. £100.

St. Thomas's Hospital.—Two Sen. Asst. M.O.'s. £600. Also Two Jun. Asst. M.O.'s. £350. Also Bacteriol. £600.

Salford Royal Hospital.—Res. S.O. £250. H.S. £150.

Scarborough Hospital and Dispensary.—Two H.S.'s £150.

Sheffield Royal Infirmary.—Hon. Radiologist. £100.

Shirlett, near Much Wenlock, King Edward VII. Memorial Sanatorium.—Res. Med. Supt. £450.

Shrewsbury, Royal Salop Infirmary.—H.S. £250.

South London Hospital for Women, South Side, Clapham Common, S.W.—Asst. P.

Stamford, Rutland, and General Infirmary, Stamford.—H.S. £200.

Stoke-on-Trent, North Staffordshire Infirmary.—Two H.S.'s. £200 each.

Stoke-upon-Trent Union.—Res. M.O. £600.

Sunderland Royal Infirmary—Jun. H.S. £200.

Sunderland, Royal Infirmary, Children's Hospital.—Female Jun. Res. M.O. £150.

Surrey County Council.—Asst. M.O.H. £600.

Throat Hospital, Golden-square, W.—Surgical Registrar.

University of London.—External Examiners.

Wakefield General Hospital.—Jun. H.S. £150.

Wallasey, Victoria Central Hospital and Wallasey Dispensary.—H.S. £250.

Woolwich Tuberculosis Dispensary, Maxey-road, Plumstead, S.E.—Asst. Tuberc. O. £500.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

Wolverhampton and Staffordshire General Hospital.—H.S. £200.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Castle Acre and at Consett.

THE Home Secretary gives notice that in consequence of the resignation of Mr. H. S. Walker, Specialist Medical Referee under the Workmen's Compensation Act, 1906, for ophthalmic cases in County Court Circuits Nos. 12 and 14, the appointment held by him is vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than April 3rd, 1920.

Births, Marriages, and Deaths.

BIRTHS.

BELLINGHAM-SMITH.—On March 9th, at 74, Kensington Park-road, W., the wife of Eric Bellingham-Smith, M.D., M.R.C.P. Lond., of a son.

BURTON.—On March 15th, at Dullatur, Camberley, the wife of Brevet Lieutenant-Colonel Colin Burton, D.S.O., R.A.S.C., of a son.

CLAPHAM.—On March 10th, at Madeley House, Park-road, Peterborough, the wife of Harold Clapham, M.R.C.S., L.R.C.P., of a daughter.

REINHOLD.—On March 6th, at Cairo, the wife of Major C. H. Reinhold, M.C., I.M.S., of a son.

DEATHS.

CHRONNELL.—On March 10th, at Hindley, James Chronnell, M.R.C.S., L.R.C.P.

CUFFEY.—On Feb. 25th, at Port Said, Egypt, Edward Cuffey, M.B., O.B.E.

DOCKRELL.—On March 15th, Benjamin Morgan Dockrell, M.A., M.D., M.A.O., Senior Physician, St. John's Hospital, Leicester-square, in his 61st year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

OYAL SOCIETY OF MEDICINE 1, Wimpole-street, W.

Tuesday, March 23rd.

)CIAL EVENING: at 8.30 P.M.

Dr. G. Murray Levick will show some of his famous Penguin Slides taken in the Antarctic during the Scott Expedition.

The Library will be open, and various objects of interest will be exhibited. Music and light refreshments. The President, Sir Humphry Rolleston, and Lady Rolleston will receive guests at 8.30 P.M. It is hoped there will be a good attendance of Fellows and their friends, who will be cordially welcomed.

MEETINGS OF SECTIONS.

Monday, March 22nd.

DONTOLOGY (Hon. Secretaries—G. Paton Pollitt, W. Kelsey Fry, J. Howard Mummery): at 8 P.M.

Casual Communications will be read by—

Mr. Frank Coleman, Mr. F. H. Doubleday, Mr. Montagu Hopson, Mr. S. F. St. J. Steadman, Mr. Harry Stobie, and Mr. Watson Turner.

Short Paper: Mr. Gerald B. Ash: Pyorrhœa.

Tuesday, March 23rd.

EDICINE (Hon. Secretaries—W. Cecil Bosanquet, J. H. Thursfield): at 5.30 P.M.

Dr. Mackenzie Wallis will introduce the subject of "Nonnephritic Albuminuria," followed by Dr. Batty Shaw and Dr. Tyson.

Friday, March 26th.

PIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—William Butler, Major Greenwood): at 8.30 P.M.

Paper: Dr. S. Monckton-Copeman, F.R.S.: Small-pox.

Those Members of the Section who wish to attend the dinner at the Welbeck Palace Hotel, at 7 P.M., are requested to notify Dr. Major Greenwood, Lister Institute, Chelsea Gardens, S.W. 1, not later than March 24th.

EDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 22nd.—8.30 P.M., Discussion on the Re-education of the Amputated, introduced by Mr. Muirhead Little.

HILD STUDY SOCIETY, LONDON, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY, March 25th.—6 P.M., Mrs. E. S. Chesser, M.D.: Adolescence and the Continuation Schools.

EDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, Cavendish-square, W.

FRIDAY, March 26th.—8 P.M., Paper: Dr. G. H. Lock: Care of Minor Ailments in School Children. A discussion will follow.

ECTURES, ADDRESSES, DEMONSTRATIONS, &c.

OYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY, March 23rd, AND THURSDAY.—5 P.M., Lumleian Lectures:—Sir J. Rose Bradford, K.C.M.G., C.B.: The Clinical Experiences of a Physician during the Campaign in France and Flanders 1914-1919. (Lectures II. and III.)

ING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).

A Course of Post-Graduate Lectures on Syphilis is being given by various members of the staff of King's College Hospital during the present year.

FRIDAY, March 26th.—9.15 P.M., Mr. H. Playfair: Syphilis in Antenatal and Obstetric Practice.

ATIONAL HOSPITAL FOR DISEASES OF THE HEART, POST-GRADUATE COURSE, Westmoreland-street, W.

MONDAY, March 22nd.—11 A.M., Out-patients: Dr. Goodall. 2 P.M. In-patients: Dr. Moon.

TUESDAY.—2 P.M., Out-patients: Dr. R. Wells. 3 P.M., In-patients: Dr. Gibbes.

WEDNESDAY.—2 P.M., Out-patients: Dr. Moon. 5.30 P.M., Lecture:—Dr. Moon: Heart Affections and the Labour Market.

THURSDAY.—10 A.M., In-patients: Dr. Hamill: 2 P.M., Out-patients: Dr. Price.

FRIDAY.—2 P.M., Out-patients: Dr. Gibbes. 2.30 P.M., In-patients: Dr. Wells.

SATURDAY.—10.30 A.M., In-patients: Dr. Hamill.

ORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, March 23rd.—2 P.M., Demonstration:—Dr. F. G. Crookshank: Cases illustrating Joint Disease in Children. 4.30 P.M., Lecture:—Mr. C. H. Hayton: Inflammatory Diseases of the Middle Ear.

ATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

MONDAY, March 22nd.—2-3.30 P.M., Out-patient Clinic: Dr. Collier. 3.30 P.M., Ward Cases: Dr. Aldren Turner.

TUESDAY, March 23rd.—2-3.30 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Dr. Tooth: Encephalitis.

WEDNESDAY, March 24th.—2 P.M., Mr. Elmquist: Demonstration of Fraenkel's Exercises. 3.30 P.M., Dr. Collier: Aphasia and Apraxia. (II.)

THURSDAY, March 25th.—2-3.30 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Ward Cases: Dr. Saunders.

FRIDAY, March 26th.—2-3.30 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Mr. Elmquist: Demonstration of Fraenkel's Exercises.

SATURDAY, March 27th.—9 A.M., Surgical Operations.

Fee for Post-Graduate Course £7 7*s*. C. M. HINDS HOWELL, Dean.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

SATURDAY, March 20th.—10 A.M., Mr. Banks Davis: Operations of the Throat, Nose and Ear.

MONDAY, March 22nd.—12.15 P.M., Mr. Burnford: Pathological Demonstration.

TUESDAY.—5 P.M., Mr. T. Gray: Congenital Hypertrophic Stenosis of the Pylorus.

WEDNESDAY.—5 P.M., Mr. Gibb: Glaucoma.

THURSDAY.—5 P.M., Mr. Baldwin: Practical Surgery.

FRIDAY.—5 P.M., Special Lecture:—Sir W. Arbuthnot Lane, Bart.: Intestinal Stasis.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY, March 24th.—4.30 P.M., Dr. Burrell: Vital Capacity in Pulmonary Tuberculosis.

CHADWICK PUBLIC LECTURES, in the Lecture Room, Royal Society of Arts, John-street, Adelphi, W.C.

MONDAY, March 22nd.—5.15 P.M., Lecture:—General Sir John Goodwin, K.C.B., C.M.G., D.S.O.: Military Hygiene in Peace and War. III., The Future of Army Hygiene (Its Relation to the Hygiene of the Civil Community). (Illustrated by lantern slides.)

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE DEMONSTRATIONS, at Sheffield Royal Hospital.

MONDAY, March 22nd.—3.30 P.M., Dr. Nutt: Ionic Medication: Radium Therapy, &c.

TUESDAY.—4 P.M., Dr. Hay: Ophthalmic Operations.

WEDNESDAY.—3.30 P.M., Dr. Wilkinson: Cerebral Complications.

THURSDAY.—3.30 P.M., Dr. Skinner: Methods of Treatment of Ear and Nose Suppurations.

FRIDAY.—4 P.M., Dr. Hay: Common Mistakes in Diagnosis and Treatment of Eye Diseases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

TUESDAY, March 23rd.—4.30 P.M., Mr. C. Roberts: Chronic Inflammations and Cysts of the Breast.

SALFORD ROYAL HOSPITAL AND ANCOATS HOSPITAL POST-GRADUATE DEMONSTRATIONS, at the two Hospitals alternately.

THURSDAY, March 25th.—4.30 P.M., Mr. Platt: Demonstrations on the Principles of the Treatment of Fractures. (At the Ancoats Hospital.)

BRIGHTON DIVISION OF THE BRITISH MEDICAL ASSOCIATION, at the Children's Hospital.

THURSDAY, March 25th.—4 P.M., Clinical Demonstration.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. G. G. Alderson, Kenilworth.

B.—Major S. T. Beggs, R.A.M.C.; Sir J. Byers, Belfast; Dr. H. W. Bailie, Belfast; Prof. W. B. Bell, Liverpool; Dr. C. L. Browne, South Mimms; Sir C. Ballance, Lond.; Dr. H. K. Brade-Birks, Salford; Colonel R. J. Blackham; Dr. G. Blacker, Lond.; Bengal Medical Association, Calcutta, Hon. Sec of; Prof. A. E. Boycott, Radlett; Dr. Browdy, Manchester; Sir J. R. Y.—Mr. M. Yearsley, Lond.

Notes, Short Comments, and Answers to Correspondents.

ARMY HYGIENE DURING THE GREAT WAR.[1]

BY SIR JOHN GOODWIN,
DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.

AFTER referring to the personal hygiene of the troops, and drawing attention to the importance of the prophylactic as well as actual reparative work carried out by the dental department, Sir John Goodwin referred to the problems of the clothing and equipment of the soldier and the provision of the three main essentials to life—namely, food, water, and air.

Problems Affecting the Individual.

In the past the military ration had been arranged upon more or less empirical lines after actual test marches. During the war, however, the importance of avoiding waste led to more exact studies of the needs of the troops by the method of indirect calorimetry. The enormous army has throughout been fed in such a manner as to provide the energy and heat required for effective fighting and to avoid outbreaks of disease traceable to the diet. For the minor outbreaks of neuritis and scurvy in those most distant areas, Mesopotamia and North Russia, the dependence on preserved food-supplies from home were accountable. Steps were quickly taken, however, to provide the necessary accessory food factors, at first by germinating pulses and by yeast, later by the intensive local cultivation of fresh foodstuffs, of as much value to the native inhabitants as to the troops. The numerous cookery schools have been attended by officers of every grade of seniority, that they might be able so to supervise the preparation of the rations issued as to provide the most suitable, varied, and appreciated meals. Moreover, it was a matter of absolute necessity to supply men in the trenches with hot meals, and this was ensured by means of jacketed hot-boxes.

Water-supply.—The question of a pure water-supply is one of the first importance. Filter candles were found to be unsuitable for active service conditions, and were replaced by chlorination. The net result of war experience was the established value for sterilisation purposes of chloride of lime in the form of bleaching powder. As the war proceeded the need for the provision to advancing troops of properly treated water in large quantities led to the development of special water-tank companies. These units are capable of collecting, filtering under pressure through sand, sterilising by chlorine gas (by means of an ingenious regulator), and transporting large quantities of water wherever the motor-lorry could move. In the same way, barges for use along the waterways of the various theatres of war were developed.

The question of *air and ventilation* are of equal importance. Pflüger's experiments showed the range of droplet infection from mouth to mouth to be somewhere within 1½ metres, and this is the range that should represent the minimum proximity of men's heads in barracks or beds. The importance of that knowledge had sometimes been submerged by reason of national necessity. However, two instances have recently shown that the principle involved—now known as "spacing-out"—cannot be disregarded. These were (1) the cerebro-spinal meningitis outbreak starting in 1915; (2) the influenza outbreak of 1918. In both these instances a populace was unavoidably concentrated, with a resultant reduction in the spacing-out, and an opportunity arose for "mouth-to-mouth" or "droplet" infection. In the cerebro-spinal meningitis outbreak, immediate spacing-out of the affected troops produced a rapid fall in the case and carrier incidence; in the same way, it was effective in reducing the high incidence of influenza on its last appearance as a pandemic. It may be of interest to note that the experience of the war has led to a reconsideration and still further enlargement of the cubic space allowed the troops, particularly overseas, and also of the correlated questions of pharyngeal and pulmonary disinfection. The importance of pharyngeal disinfection was early recognised, and all transports were provided with special inhalation chambers. It is intended that these shall be a permanent feature of transports in the future, and it is of interest in this connexion to note the recent encouraging reports from industrial works of the value of certain gases, inhaled in insensible but definite amounts, in inhibiting the incidence of influenza and allied respiratory disorders.

Problems Affecting Particular Groups.

So much, then, for questions affecting all the troops. Now we come to the more special problems affecting particular groups of soldiery, and perhaps the most important is the control of outbreaks of infectious disease. Cases of infectious disease in war areas were immediately isolated in well-staffed and equipped isolation hospitals behind the line. Special dysentery centres were arranged whither all cases of diarrhœa were immediately removed and kept under observation; if diagnosed as dysentery they were notified, evacuated down the line and isolated; otherwise they were returned to duty on recovery. The administrative sanitarian was thus enabled to locate foci of infection, to trace continuity between areas, and generally to decide where executive sanitary action was necessary.

Epidemic disease—with the exception of the influenza pandemic—was noticeably absent, and the care taken to filter off unfits on the lines of communications went far to explain the remarkable freedom from disease of the men in the line. The problem of the excremental diseases was approached in two ways—firstly, by the general inoculation of the troops so as to provide a relatively high immunity to enteric, and secondly, by the careful disposal of all infected matter. No little credit must be accorded to regimental and medical officers for their part in educating the men to the value of inoculation, and in overcoming the natural—or inspired—reluctance to what has in our army remained a purely voluntary measure.

The associated problems included the safe disposal of all excrement, the purity of the water-supply, the safeguarding from dust and flies of food stores, and the elimination so far as possible of flies. Incineration of excremental matter proved to be the surest and safest method of disposal in the absence of a water-carriage system, and this method has developed into something of an exact science.

The fly question, especially in the Eastern theatres, was a vast and difficult one, in view of the quantity of horse litter inevitably associated with the army, and frequently of the tactical or climatic impossibility of burning such fertile breeding matter. Ingenious methods other than burning included the utilisation of horse litter as the basis of desert roads, built up by the addition of a top layer of clay, which becomes compacted under the pressure of traffic; or, again, the compacting of litter into wind-proof walls utilised as screens for the stables of animals otherwise unprotected. The study of substances intended for fly destruction, including the "bottle flies" and "flesh flies," associated with the corpses in No Man's Land led to the adoption of the most satisfactory materials; and the knowledge thus gained will doubtless prove of value to the community as a whole.

Insect-borne Diseases.

There was a considerable wastage in all theatres of war from insect-borne diseases of different types. In France, much of the minor sickness of the troops was traceable to louse infestation, from various septic skin conditions to trench fever. The sufferings of our Allies the Serbs from typhus fever also emphasised the necessity for a vigorous campaign of disinfestation. The problem was met largely by the provision of facilities for bathing at frequent intervals and by the increase in facilities for disinfecting personal clothing and blankets. Later dependence was largely placed on portable spray baths. The development in methods of disinfection by steam in the latter part of the war culminated in the use of the Foden-Thresh apparatus, comprising two large Thresh disinfecting chambers mounted on and operated under slight pressure by a Foden steam-lorry. The apparatus could move rapidly to any area in which it was required, commence operations at once by turning the steam into the chambers, and then drive to a fresh centre for operations. In areas where road conditions were less suitable for lorry transports disinfectors were improvised from the native wine barrels; or, in the more settled units, improvised hot-air disinfectors were adapted to dug-out conditions. The value of hot air is now established, and the latest "Orr hot-air huts" are models of efficient disinfectors.

The steps taken in the prevention of malaria, the sanitary arrangements in the trenches and in billeting areas were well organised, and the Sanitary Section also did valuable service in effecting certain economies. For example, by the careful collection in special cold-water grease-traps of wash-up fat, and of the scrap-fat and bone-fat rendered in cookhouses, a bulk of crude fat was obtainable which proved of immense use in the manufacture of soap and of glycerine.

Among the adjunct means of sanitary control were the hospital clinical and mobile laboratories, both "bacteriological" and "hygienic"; the latter were mounted on motor-lorries and capable of proceeding rapidly to undertake investigations in any part of the area served by them. Attention must also be drawn to the preparation of the millions of doses of vaccines used throughout the armies, as well as to the researches on dysentery, epidemic jaundice, and other subjects. The Medical Research Committee is ublishing many of the results of war studies. In 1916 the lied Governments formed the Inter-Allied Sanitary Com- ission to discuss common problems, to make known the sults of effort or experiment, and so to effect mutual öperation. Certain delegates were appointed to meet onthly for discussion in greater detail than was possible at e full annual meetings. Many of the Allied nations were us enabled to apply measures of prevention, successfully rried out by others, with which they were at the time familiar.

---

[1] Being an abstract of the second of three Chadwick lectures on Military Hygiene in Peace and War, delivered on March 15th, 1920. The first lecture appeared in THE LANCET of March 13th.

By the labours of the united profession, all doing that work hich was required of them and which local authority nsidered most immediately necessary, the troops in this ar were served as few armies have ever before been served.

HOME HEALTH RESORTS.

A LETTER in THE LANCET of Feb. 28th announced the rthcoming International Congress at Monaco, at which the bjects to be discussed are Medical Hydrology and Geology, ygiene and Climatology, Spas and Thalasso-therapy. Those ho attend will hold a watching brief for the health sorts of Great Britain, and the secretary of the Organising mmittee asks whether, in so far as the benefit of cure is derived from complete change in the patient's bits and surroundings, it is not time for Great itain to cater for those who used to flock to Central urope. As long ago as 1908 Dr. Neville Wood sug- sted in our columns that if the Channel proved an cellent barrier between our patients and their worries mongst which may usually be included their relatives and iends) it should also be made to serve reciprocally for our reign visitors. He pointed out that while it is obviously eless to try to keep in England those who yearn for the rm sun in mid-winter we should redress the adverse lance by encouraging an interchange of invalids. Most unicipalities exhaust themselves in the vain attempt to ep the British from foreign spas, but make no efforts to pularise their towns abroad. The literature describing our as is written in English only. Foreign manuals of European alth resorts hardly mention them, not through ill-will, it in many cases after an unsuccessful endeavour to obtain e necessary information. There has been a development Anglophilia among the French and Italian during the ar, and if the amenities of some of our spas were only own to them there would probably be no lack of visitors.

If we review our position it becomes clear that we cannot mpete with the triple combination of climate, scenery, d elegance offered by Biarritz, St. Moritz, and the Riviera. gain, the waters of our inland resorts are in no way peculiar this country, but are of types equally well represented on e continent. But as we have pointed out before, one big lvantage exists in that nearly every place in Great Britain at its best in the hot summer months, at the season when ntinental places are often at their worst, at any rate from e standpoint of active exercise in the open air. There are w chronic diseases now in which the treatment does not clude mild exercise in the fresh air. Modern research and periment have shown its special value, for example, even heart cases, where complete rest was formerly advised.

Among the attractions of our health resorts are the cellent links by which they are usually surrounded. To e golf enthusiast weather matters little; moreover, since cent researches have established the tonic value of cool oving air, our much-abused climate may in the future be ught even for that variability so dreaded in the past.

As regards balneo-therapy our hydropathic institutions ed fear no comparisons, but with such a long and tractive coastline it is surely in thalasso-therapy that we ould attempt to specialise. In this respect we are not ry enterprising. Towns which have spent much money elaborate parades and drives along the sea-front make it little provision for the convenience of sea-bathers. The ivate tent or hut, which is now supplanting the old thing machine, has at least one disadvantage—that embers of the family cannot be in the water all at the me time, and that the prearranged time-table often leads a condition of blue shivers in the last man out.

Colonials visiting our seaside places are often amazed at e primitive arrangements. In a Natal resort, for instance, e bathing-huts are roomy and well lighted, fitted with elves and mirrors as well as hooks, and divided into an ner carpeted and an outer sloped compartment. The tter is provided with a bucket of fresh water and a small stern on the roof for a shower-bath, while the attendant rns on an electric hair-drying apparatus if desired.

We do not suggest that the pleasure of a swim is really uch enhanced by all this luxury, but while most of us are epared to bathe off the beach, with a rock as shelter, reigners are undoubtedly attracted by elaborate dressing- oms. Few will deny that the sticky, gritty feeling which mains after a rub with a towel the size of a handkerchief tracts somewhat from the refreshment of a sea bath. For e rest, swimming regattas and water-polo might be couraged by the presentation of challenge cups, and on certain shores a modified form of surfing could probably be introduced.

There is one other point needing attention if foreigners are to be attracted—the food at our seaside hotels. The farce of a long, elaborate menu, written in language as unfamiliar to our Allies as to ourselves, and as doubtful in origin as are the dishes it indicates, should be abandoned. The substitution of a three-course dinner would be welcomed, we believe, by all visitors, of whatever nationality. Foreigners do not want so-called French pastries and sauces in England, and appreciate a complete change of diet. The only complaint they are likely to make is of the monotony of the vegetables served.

NATIONAL SCHEME FOR THE EMPLOYMENT OF DISABLED MEN.

THE first edition of the King's National Roll, which has just appeared, contains the names of some 10,000 employers who have undertaken to provide work for disabled men under the National Scheme. This represents in the aggregate 1,500,000 workpeople, including nearly 90,000 disabled men. Since Dec. 31st, when the list went to press, it is stated that the number of employers registered has grown to over 12,000, but the supply of disabled men is unhappily by no means exhausted. There are thousands still in hospital, for whom livelihood employment will have to be found. Copies of the Roll may be seen at employment exchanges, free libraries, and other public buildings, and are to be purchased from H.M. Stationery Office at 1*s*. 6*d*.

THE POSITION OF POTASH SUPPLIES.

IN an article in this column in THE LANCET of Feb. 14th we referred to the possibility of potash deposits being found in certain English counties where rock-salt occurs in abundance. The Germans were long ago persuaded that potassium salts were probably associated with the common salt deposits in that country, and that proved to be the case. Such a finding, we suggested, should stimulate investigation in our salt districts. We have since received an interesting communication from the Alsace-Lorraine Development and Trading Company, who state that the Alsatian deposits of potash salts extend over an area of 50,600 acres. They are situated in the region of Cernay and South Mulhouse, and consist of layers of a thickness of from 8 to 18 feet at a depth of from 1600 to 2300 feet. According to the most conservative estimates, the lower layer alone should yield 2000 million tons of potash salts, equal to 300 millions of pure potash (K_2O), which is about 400 times, it is stated, the annual pre-war consumption of the whole world. This should be good news for the agricultural industry. Sylvinite, the name of the deposit, is a mixture of rock-salt and potassium chloride, the yield of the latter being from 50 to 60 per cent. The output will be increased as the damaged state in which the Germans left certain of the mines is restored.

The following note in the *Economic Review* (March 3rd) is of interest in connexion with these particulars :—

> *Potash Output in Alsace.*
>
> According to the *Berl. Tagbl.*, the potash output in Alsace varies from 4000 to 5000 t. per day. Large orders are coming in, but, owing to the continued transport difficulties, barely 2000 to 3000 t. can be despatched daily. The purchasing syndicate of the Alsatian Potash Works is at Mulhouse, and bears the name of "Société Commerciale des Potasses d'Alsace-Lorraine." (*Frankf. Ztg.*, Feb. 14th, m. ii.)

France has evidently gained a large asset in the mineral resources of her restored provinces, and the breakdown of the great German potash monopoly of pre-war times is clearly threatened.

THE VALUE OF REST IN THE TREATMENT OF GONORRHŒA.

IN a recent number of the *Medical Journal of Australia* appears an article by Major W. L. Potter, of the Australian Medical Service, on the Influence of Treatment and Rest on Gonorrhœa. It is based on the study of 365 acute cases treated during a long period of duty in 1916. Particular attention has been paid by the author to the incidence of epididymitis, since the occurrence of this complication in a case doubles the period required for its cure. A comparison is made of the various systems of treatment employed at No. 5 Australian General Hospital, the value of the different methods of treatment being determined by two criteria: first, the percentage of cases developing epididymitis; secondly, the time taken to effect a cure. A system of treatment aimed to avoid complications such as epididymitis may raise the average time taken to effect a cure. Conversely the adoption of a more drastic system of treatment may shorten the average time of cure, but at the same time produce a greater number of complications. The ideal system is therefore one designed to cure the urethritis in the shortest period compatible with the avoidance of complications. As the result of a careful analysis of the series of cases under his care Major Potter has arrived at the following conclusions: (1) that suitable treatment has a favourable effect on disease; (2) that the most important factors in the avoidance of complications are rest and abstention from urethro-vesical irrigation during the earlier stages of the disease; (3) that diet and medicines are of secondary importance; (4) that prostatic massage and vaccine therapy are of no utility; (5) that no system of outdoor treatment will produce satisfactory results unless facilities for rest are provided.

PUBLIC HEALTH IN CALCUTTA, 1918.

THE number of deaths in Calcutta during 1918 reached "the appalling total" of 31,371, equivalent to [illegible] death-rate of 35 per 1000, calculated on the census population of 1911; this ratio was higher than in any year since 1907, and in strong contrast to that of 1917, which was 23·8, the lowest hitherto recorded. The ratios require to be modified according to the increase of population during seven years since the census, but the actual number of deaths compared with those of the previous year (21,360) points unmistakably to the presence of a severe and widespread epidemic—i.e., influenza—which broke out in June, and again with increased virulence in September. The deaths registered as due to this cause were 4115, but Dr. H. M. Crake, the medical officer of health, considers that at least 2000 should be added to this figure, as there was an excess mortality of 2500 under the headings of respiratory diseases and fevers. The ratios of death from all causes varied in different parts of the city from 11·7 in Park-street Ward to 44·7 in Entally, and 64 in Kidderpur; in 20 out of the 25 wards the ratios were over 30 per 1000, whereas in 1917 only one ward had a ratio over 30. The female mortality was 44·1, compared with 30·6 for males, but there was not such a relative disparity between the sex ratios as in 1917, when they were respectively 32·1 and 19·8, or as in the quinquennium 1913–17, when they were 36·2 and 22·5 Though the actual difference is greater, the relative difference is not so marked. The male ratio (1917) was increased by 54 per cent.; that amongst females by 37 per cent. About two-thirds of the inhabitants are Hindus, with whom the death-rate was 37·5; among Mohammedans it was 30·5; among non-Asiatic Christians, 25·6. It is stated that these latter had no immunity from influenza attacks, but apparently an increased power of resistance and lessened liability to complications and sequelæ. The heavy mortality among females, especially from tuberculosis (2·9 per 1000, compared with 1·6 among males), due to the insanitary purdah system, by which the women are confined in the almost invariably ill-lighted and ill-ventilated zenana, has been repeatedly pointed out.

Infantile Mortality.

The infantile mortality ratio was 280 per 1000 registered births. In three wards it exceeded 400 per 1000, but defective birth registration is considered to be partly responsible for these "appalling figures. ...... With excessive overcrowding, a local outbreak of small-pox, and two epidemics of influenza, the babies born in this densely-packed agglomeration of insanitary buildings have had very little chance of surviving." In Jorabagan Ward the ratio was 581 per 1000. Of the 5096 deaths among infants in the whole city 1791 died before they were a week old, nearly all from "congenital debility" (769), premature birth (545), or tetanus neonatorum (395). It is pointed out that the prevention of this last-named cause is perfectly feasible; "it is unknown amongst cases attended by Corporation midwives." Bronchitis caused 1483 infantile deaths (29 per cent. of total), due to insufficient clothing; but diarrhœa caused only 280 deaths (5·4 per cent.), because breast-feeding is almost universal.

Plague, Enteric, Influenza, &c.

Plague deaths numbered 210 (0·23 per 1000) compared with 81 in 1917. The disease was imported by immigrants from Rajputana and elsewhere into the already crowded Burra Bazar district, and was localised in this and the immediately surrounding sections. Cholera caused 1526 deaths (1·7 per 1000), also a considerable increase on the previous year (866 deaths, 0·96 per 1000). All districts of the city were affected, but most deaths occurred in the wards bordering on the river or on the grossly polluted stream known as Tolly's Nullah, which is really an open sewer. It is, however, "considered peculiarly sacred [i.e., by Hindus], and bathing in it is an essential part of various festivals, which attract numerous pilgrims." The deaths among Hindus numbered 1295 (2·1 per 1000), among Mohammedans 214 (0·88 per 1000).

Under enteric fever were registered 345 deaths (0·38 per 1000), a considerable increase over the mortality from this disease during the four years immediately preceding, in which the ratio had varied between 0·21 and 0·28; in 1913 it had been 0·39. The deaths occurred chiefly in July and October; the epidemic prevalence of influenza showed itself in June and September. Dr. Crake very reasonably supposes that this influenza prevalence lowered the powers of resistance, so that many cases of enteric died that, influenza being absent, would have recovered. "A lowering of the general powers of resistance not only means that the minimal lethal dose of a bacterial toxin is relatively smaller, it also means that the amount of infection capable of causing the disease is also relatively smaller. In other words, it is not only easier to kill a man whose powers of resistance are lowered, it is also easier to infect him. ...... Hence the general rise in the mortality, under almost all headings, which has followed the outbreaks of influenza." This lowering of vitality is probably the most serious factor in influenza infection, and treatment appropriate to the condition that may ensue is of the greatest importance. It is to be noted that "Non-Asiatics and Anglo-Indians," with a ratio of 0·65 deaths per 1000 from enteric fever, suffered much more than Hindus (0·48), and these, again, more than Mohammedans (0·10); there was probably increased susceptibility, as Dr. Crake suggests. Malaria showed some increase, 1·3 deaths per 1000, compared with 1·1 in 1917. The wards most affected by malaria and "other fevers" are suburban wards with tanks, surface drains, &c., that provi mosquito breeding-places.

Increase in Tuberculosis Death-rate.

Tuberculosis had declined from a death-rate of 2·5 per 1000 i 1913 to 1·7 in 1917; in 1918 it rose to 2 per 1000, the number of deat being 1826. No doubt this was due to the influenza outbreak. I two wards (Entally and Beniapuker) the rate exceeded 3 per 100 Ill-ventilated houses and promiscuous expectoration make sprea of the disease practically inevitable. Indian Christians, with mortality of 4·8 per 1000, suffer much more than Mohammeda (2·1) or Hindus (1·9). Being cut off by their orthodox relatives o embracing Christianity, they often have a hard struggle to live, an overcrowd certain localities; everyone "spits promiscuously a over the place," and spread of the disease is inevitable. In the ag period 15 to 20 years the male death-rate from tuberculosis was 1 and for females 4·9 per 1000; from 20 to 30 years the ratios were 1 and 4·9; from 30 to 40 years 2·2 and 4·7. "The chief cause of th appalling mortality amongst women is the purdah system mai tained in insanitary houses in the slums of a great city."

Respiratory Diseases.

Respiratory diseases caused 6914 deaths, compared with 47 deaths in the previous year, the respective ratios being 7·7 and 5·3 p 1000. The bulk of the increase was due to the influenza epidemic resulting in fatal bronchitis or pneumonia In Kidderpur Ward th respiratory death-rate was 15 per 1000, that for influenza being 22·7 the actual numbers for these two diseases were 329 and 496 respe tively. The beginnings of the influenza epidemic in June could n be definitely localised; the early cases were of a mild characte and the disease is not compulsorily notifiable. "The lightning-lik rapidity with which it spread all over the city baffles descriptio ...... All classes of the community in all parts of the city wer attacked." The municipal services were disorganised, approx mately 50 per cent. of the staff being infected. Three types wer distinguished: (*a*) typical, with the usual symptoms; (*b*) a for resembling dengue, with fever, pains all over the body, profu perspiration, and marked prostration; (*c*) intestinal, with vomiti and diarrhœa. A second outbreak occurred in the middle September, which lasted until December. The disease sprea slowly, but respiratory complications were more frequent and th case-mortality considerably higher. Over a hundred relief centr were established, as well as 50 travelling dispensaries. Fi types were distinguished: (*a*) simple febrile; (*b*) respirator (bronchitis, pneumonia); (*c*) circulatory (high fever, tendency syncope, generally fatal); (*d*) abdominal (diarrhœa, dysenter (*e*) nervous (delirium, coma, death). A total of 164,695 patients we treated up to Dec. 31st, 1918. According to one estimate the cas mortality rate was 24·5 per 1000; according to another 34·4 per 100 Dr. Crake considers that the mean of these two rates—that is, abo 3 per cent.—is approximately correct.

Summary of the Report.

Many other subjects are dealt with in Dr. Crake's repor which is fully illustrated with tables and diagrams, and ha a plan of Calcutta, showing the relative mortality in th various wards. The difficulties of administration that hav to be overcome in dealing with epidemic emergencies suc as have been mentioned would not be lessened in a climat like that of Calcutta, where the mean *minimum* monthl temperature was above 75° F. from May to Octobe inclusive, and the mean *maximum* was above 87° fro March to October inclusive. In June there was [illegible] fall 16 in. of rain, and the mean minimum temperature wa 78°, conditions most favourable for the incubation pathogenic germs. The effectual carrying out of the detail of sanitary administration among a population such [illegible] tha of Calcutta and under these climatic conditions present difficulties that are obvious. The medical officer of healt is to be congratulated on the excellent results that hav been attained.

THE R.A.M.C. VIEWS ON VENERY.

To the Editor of THE LANCET.

SIR,—I have lately been reading [illegible] book by Stephe Graham entitled "A Private in the Guards," and foun therein (pp. 255–6) a statement which ought to be challenged He writes that the army chaplains "could not inveig against lust because the medical officer was of opinion tha Nature's needs must be satisfied." "Sexual intercourse wa regarded as a physical necessity for the men. Beside being the medical point of view, it became the officia army point of view as well, and we were often told i lectures that it was natural, and all we had to do was to us the safeguards and preventatives which were at our disposal to save us from disease." "Hundreds of thousand were even encouraged to go with impure women." believe, Sir, the exact contrary is held by the bulk of th medical profession in this matter. Such a travesty of trut seems calculated to have a pernicious effect on the reader of this remarkable book. If the author really has an backers in the R.A.M.C. they should speak for themselves.

I am, Sir, yours faithfully,
H. KENNEDY SMYTH, M.B., B.Ch., D.P.H.,
Umtali, Rhodesia, Jan. 31st, 1920. District Surgeon.

In Memoriam.—The names of the Representative Committee constituted to put into execution a scheme fo erecting a permanent memorial to the officers, non-commissioned officers, and men of the Royal Army Medical Corp who fell in the war (referred to in the annotation i THE LANCET of March 6th) were printed in THE LANCE of May 3rd, 1919, p. 766.

Hunterian Lecture

ON THE

LATE RESULTS OF THE SURGICAL TREATMENT OF CHRONIC ULCERS OF THE STOMACH AND DUODENUM.

Delivered before the Royal College of Surgeons of England on Feb. 11th, 1920,

BY JAMES SHERREN, C.B.E., F.R.C.S.ENG.,
HUNTERIAN PROFESSOR AND MEMBER OF COUNCIL, ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO THE LONDON HOSPITAL, ETC.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—That the surgical treatment of chronic gastric and duodenal ulcer leads to the immediate alleviation of symptoms is now one of the commonplaces of surgery, and has even found its way into contemporary fiction. Every surgeon, however, who follows up his cases meets with those in whom, after a period of immediate relief, symptoms reappear. These are usually trivial and of short duration, but are occasionally serious and long continued, the result of ulceration in the region of the anastomosis. So much does this group appeal to the imagination that our junior vice-president lectured here four years ago on "Ulcers Old and New: Jejunal for Duodenal."[1]

I am confining myself to consideration of the results in cases personally operated upon. Only in this way is there the assurance that the technique and method of treatment, although varying with increased experience, remained identical in each series, and that the condition and situation of the ulcer is accurately known.

Surgical treatment has not, and cannot, become mechanical; every chronic ulcer needs individual consideration. It is not a case of "Here is a chronic ulcer, let us do a gastro-jejunostomy." This fact requires emphasis, as it is by no means unusual for a case to be sent to the surgeon, not for treatment, but with the request that gastro-jejunostomy should be performed. The impression that this operation is a cure for all gastric ills led to its falling to a certain extent into disrepute.

A recent paper by Dr. Robert Hutchison[2] on Disappointments after Gastro-jejunostomy led to an interesting discussion in subsequent issues of the *British Medical Journal*, and an adequate surgical summing up by Sir Berkeley Moynihan.[3]

The result of the surgical treatment of chronic ulcer of the stomach and duodenum is equal to that of any major operation in surgery. Gastro-jejunostomy will fail if carried out in unsuitable cases, just as removal of the appendix fails to cure pain in the right iliac fossa that is not due to disease of that viscus; even in suitable cases the accident of an adhesion may lead to an attack of intestinal obstruction years later.

I intend to review the result in those patients who have been operated on over two years. I have selected this period for two reasons: (1) in many of the cases under discussion adequate rest in bed and medical treatment would have been followed by the disappearance of symptoms for a considerable time; it is safe to say that it would not be as long as two years; (2) it is most unusual for symptoms to reappear for the first time at an interval of more than two years after operation, and most of the cases of secondary ulceration have occurred within this period. In 1912[4] I reviewed 72 consecutive cases operated on more than two years before. I have been able to trace all those of chronic duodenal ulcer that I was then in touch with. All that were quite well have remained so, and two who were not absolutely well now call themselves cured. Two also of the cases operated upon for chronic gastric ulcer who were not "quite well" have now lost their minor discomforts; one only of those who were successes have had further symptoms; this patient died of abdominal malignant disease seven years after operation. Four have been lost sight of after remaining well for 5, 6, and 11 years. Three died of other causes, and in two I was able to obtain a post mortem; in both the ulcer had healed and the anastomosis was perfect. I therefore do not consider it is running any grave risk of exaggeration if I consider those remaining well for two years as successes.

THE OPERATION OF CHOICE.

That gastro-jejunostomy alone is sufficient in many cases is certain. Hutchison[5] states: "The modern operation of gastro-jejunostomy when performed for chronic ulcer of the stomach or duodenum is usually so satisfactory in its results that a surgeon is justified in promising the patient complete relief from his symptoms if he submits to it." This would be still more in accord with present experience if the words "of gastro-jejunostomy" were omitted.

In 1914,[6] in a contribution to a discussion on the treatment of chronic gastric and duodenal ulcers, I said: "The operation to be performed on any individual case can only be determined after the abdomen is opened." This holds good at the present time, although gastro-jejunostomy is still the operation of choice in the majority of cases. When this operation is performed it should be the posterior no-loop vertical. This will bring about permanent healing in "free" ulcers; those that have perforated and have an adherent base or floor formed usually of liver or pancreas do not completely heal after this procedure alone. When gastro-jejunostomy is indicated and the posterior method is impossible, the anterior no-loop that I described in 1907[7] gives equally good results. I have done this in 40 cases, the majority before 1912. Most that I then considered suitable I now treat by partial gastrectomy.

Gastro-jejunostomy acts by its influence on gastric motility and secretion. It secures a more rapid emptying of the stomach, and so prevents or counteracts pyloric spasm, and should abolish the excessive acidity which, with gastric stasis, Bolton[8] has shown to be a cause of chronic ulceration.

It is important that the opening should be large (I make it from 2½ to 3½ inches), and situated so as to give the best result in lowering acidity. The site of election is at the cardiac end of the pyloric segment of the stomach, immediately above the duodeno-jejunal flexure. In 11 instances in which for various reasons I have had to make the opening nearer the pylorus than usual, the post-operative lowering of gastric acidity has not been so marked, and has in some instances been wanting. A temporary increase has even been noted. The following is an example:—

T. H., a male, aged 36. Operation Dec. 17th, 1918, for chronic duodenal ulcer. The opening was made nearer the pylorus than usual on account of close adhesion of jejunum to the under surface of transverse mesocolon. Gastric acidity before operation. Free HCl 0·18. Total acidity 71. Jan. 1st, 1919: Free HCl 0·22. Total acidity 77. I had to readmit him five months later with some return of pain. He is now free from symptoms with a gastric acidity 0·15 and 65.

I have notes of 174 patients in whom test meals were given both before and after gastro-jejunostomy only had been done. All the examinations were carried out in the London Hospital Clinical Laboratory, under Dr. P. N. Panton, by the method he described with Dr. H. L. Tidy.[9] The normal gastric acidity by this method is free HCl 0·08 to 0·12, and total acidity between 40 and 50. I am much indebted to Dr. Panton and his assistants for the care with which these investigations have been made.

In 159 patients gastric acidity was lowered. In 99 free HCl was absent and total acidity below 30. The most marked reduction has occurred in those cases of chronic gastric ulcer situated high on the lesser curvature, so that the gastro-jejunostomy has had to be performed well to its cardiac side. It was this observation that led me to the conclusion that the greatest post-operative lowering of acidity was obtained when the opening was toward the cardiac end of the stomach. The result within a few weeks is striking.

On May 29th, 1918, I operated on a male, aged 42, with a chronic ulcer high on the lesser curvature. Gastric acidity was reduced from 0·1 and 48 on May 13th to absence of free HCl and 7 on June 24th.

On Dec. 14th, 1917, I operated on a woman of 35 for a similar condition. Her gastric acidity fell from 0·09 and 57 on Dec. 11th to absence of free HCl and 10 on Dec. 29th.

The same reduction is seen after operation for chronic duodenal ulcer.

W. E. S., a man of 37. Operation 16/7/16. Gastric acidity on July 7th 0·16 and 74. On July 25th absence of free HCl, total acidity 17.

E. N., a woman, aged 45. Operation 18/12/17. Test meal Dec. 10th, 0·22 and 80; Jan. 1st, absence of free HCl and total acidity 18.

When the anterior long-loop operation is done acidity is not so effectually lowered.

W. H. C., male, aged 37. Operation for chronic duodenal ulcer on June 17th, 1919. The transverse colon was closely adherent to the posterior abdominal wall and I had to do the antecolic operation. (It is never wise to dissect the colon away in these cases, better to run the slight risk of jejunal ulcer than the enormous one of regurgitant vomiting.) Gastric acidity on June 13th, 0·16 and 60; on July 7, 0·09 and 46.

The reduction of acidity is as great when the anterior no-loop operation is done well to the cardiac end of the stomach.

On May 6th, 1913, I operated on a man of 68 with a very scarred ulcer on the lesser curvature, adherent posteriorly but not perforated. His condition would not permit the ideal treatment of partial gastrectomy. I therefore did the anterior no-loop operation as room could not be obtained posteriorly. Acidity was reduced from 0·18 and 71 to 0·0 and 31 three weeks after operation.

I believe that this reduction in gastric acidity as the result of gastrojejunostomy is permanent. The opportunity, however, of examining gastric contents at remote periods after operation is difficult to make in the absence of symptoms. I have been able to do so in 26 patients from four to nine years after operation, and found gastric acidity still low. The following is an illustrative case:—

Male, aged 39. Operation July 7th, 1912. Gastro-jejunostomy for chronic duodenal ulcer. Before operation gastric acidity 0·2 and 79. Three weeks later, absent and 32, and in September, 1919, absence of free HCl, total acidity 25.

In none of the cases was pyloric exclusion practised. I do not consider that it adds in any way to the efficacy of the operation. It has no bearing on the healing of the ulcer, and the continued patency of the new opening has no relation to pyloric stenosis. I have post-mortem records of eight of my cases from two to nine years after operation for ulcer situated at a distance from the pylorus; in no instance did the anastomotic opening show any sign of contracture.

COMPLICATIONS AND THEIR CAUSES.

Stricture of a gastro-jejunostomy opening is the outcome of marginal ulceration due to the use of unabsorbable suture material. In the five cases of this nature that have been under my care silk or thread had been used for the inner layer of sutures in each patient.

The present technique has almost entirely abolished immediate complications. Regurgitant vomiting is now a rare incident, and is very unusual when no abnormality is noticed at operation.

The type of regurgitant vomiting which, starting at once, continued until further operation brought relief or death occurred, should have disappeared. It is due to error in technique. Vomiting within the first 48 hours is now unusual, and if troublesome usually yields readily to lavage. If occurring about the ninth or tenth day it is of more significance, and indicates that some mechanical change in the region of the anastomosis is taking place during healing. It is, however, infrequent, and in most instances ceases at once on lavage.

Among 769 patients (477 duodenal, 292 gastric) treated by gastro-jejunostomy for simple ulcer up to the end of 1919, I have had to re-operate for this cause in 7—2 duodenal and 5 gastric. The larger number in the smaller gastric group is due to the fact that the exact site of the anastomosis is here governed by the ulcer, and hence may not be so perfect mechanically as in the duodenals in whom it can be selected.

It will be seen in the following notes of cases that in all except one some unusual feature was noted, and in all some definite mechanical cause was found at the second operation.

The first instance among the duodenals arose in October, 1914, in a male of 51. I noted "the transverse mesocolon was contracted and the jejunum closely adherent to its under surface." I had to free both before doing the anastomosis. The immediate post-operative course was uneventful; no vomiting until the evening of the tenth day. Typical regurgitant vomiting started and was not influenced by lavage. I re-operated on the thirteenth day. I found that the transverse colon had again become adherent, constricting the anastomosis, and did a lateral anastomosis with great difficulty, but he died a few hours later.

Since this date I have operated on eight patients with a similar condition of mesocolon, and in each instance, whether of partial gastrectony or gastro-jejunostomy, have brought the jejunum in front of the transverse colon.

The next is the most unsatisfactory result I have had among my patients with chronic duodenal ulcer.

In January, 1918, I operated on a man, aged 40, who had had symptoms of ulcer for 20 years. I found very extensive ulceration on both surfaces of the first part of the duodenum with a dilated stomach. The mesocolon was very vascular and I noted that there was considerable difficulty in finding room for the anastomosis, and that there was oozing from the cut edge. For the first nine days there was no vomiting and convalescence was normal. On the tenth day there was one large bilious vomit, then no more for three days, then typical regurgitant vomiting set in unchecked by lavage. I re-operated four days later and found the anastomosis was constricted at its centre by a band which passed from the mesocolon to the mesentery of the jejunum. I considered it probably due to organisation of blood clot. I divided the constriction transversely and sutured it vertically and he was able to leave the home within three weeks. He has since had to be operated on twice for jejunal ulcer.

The following cases occurred among the chronic gastrics. The first was one of my early patients and I did not appreciate anything abnormal at either operation.

Male, aged 36. Operation Nov. 7th, 1905, for chronic ulcer at the centre of the lesser curvature. Vomiting started the day following and continued, although relieved somewhat by lavage until his second operation in February, 1906. He is now, and has remained, perfectly well.

In the remainder the cause was obvious.

Male, aged 40. Operation Feb. 23rd, 1912, for chronic ulcer on lesser curvature and posterior surface near pylorus. I noted troublesome oozing from the cut edge of the transverse mesocolon. Regurgitant vomiting started on the evening of the tenth day and continued unrelieved until March 3rd, when I reoperated. There was much thickening around the anastomosis and its limbs were drawn together. My notes say: "Is this due to the oozing?" Before doing a lateral anastomosis I made an incision into the stomach to exclude the possibility of gastro-jejunal ulceration; the line of anastomosis was perfect and the gastric ulcer healed. He died of another cause five years later, having remained perfectly well.

Woman, aged 50. Operation for hour-glass stomach, Feb. 25th, 1913. Posterior gastro-jejunostomy done to the largest cardiac pouch I had ever seen. She remained perfectly well until the ninth day when typical vomiting started. I reoperated March 3rd. The anastomosis had disappeared from view pulling the meso-colon up with it owing to the contraction of the hitherto dilated pouch. Lateral anastomosis stopped the vomiting at once and she has remained perfectly well.

Woman, aged 38. Operation Nov. 12th, 1915. Anterior no-loop gastro-jejunostomy for posterior ulcer. Vomiting started on the tenth day. As it was not kept under entirely by lavage I reoperated a month later, and noted that the jejunum was constricted where it passed through the great omentum. She has remained perfectly well.

Male, aged 55. Posterior ulcer excised Jan. 18th, 1916, and to the opening left the anastomosis was done. It did not lie well and appeared to be kinked. Vomiting started on the eighth day. Lateral anastomosis was done on Feb. 1st, and he remains perfectly well.

GASTRO-JEJUNAL, OR ANASTOMOSIS ULCERATION.

Before dealing specifically with the results of the operative treatment of gastric and duodenal ulcers, there is one further complication that needs special notice—secondary ulceration. First described by Braun in 1899,[10] one of the most important contributions to our knowledge was made by Paterson[11] ten years later. In addition to reviewing the recorded cases, he suggested the classification into jejunal and gastro-jejunal ulcers. This classification should always be adhered to in reporting cases. The term "jejunal ulcer" is still used loosely to include both varieties. I consider this separation is essential to the understanding of the subject and to the elucidation of the causation of this troublesome condition.

Unabsorbable Suture as a Cause.

That gastro-jejunal, or anastomosis ulceration, as I prefer to term it, is due to the presence of an unabsorbable suture is now generally recognised. The first case of this nature appears to have been operated upon by Berg in 1898, but was not recorded until nine years later.[12] Carman and Balfour[13] in a study of 13 cases of secondary ulceration at the Mayo Clinic found 6 in which unabsorbable suture material was present. The experimental work of Soresi[14] shows that unabsorbable sutures may cause gastro-jejunal ulceration when used for the inner layer. Even when catgut is used for this layer the outer thread or silk stitch may ulcerate through. This was the cause of all the anastomosis ulcers in my own cases; I have never used anything but catgut for the inner layer. The fact does not yet appear to be generally recognised, for unabsorbable material is still being used for the outer layer by many surgeons.

It is impossible to estimate the frequency with which these ulcers occur, as it must vary with individual technique and in the anastomosis variety it is possible for the offending stitch to be evacuated naturally. Secondary ulceration is a rare complication, but each case impresses itself on the mind of the surgeon as a failure, although further operation may convert it into a success.

I have a personal operative experience of 31 cases. In 23 the original operation was done by myself; 27 followed gastro-jejunostomy for duodenal ulcer. This is very striking, and has been noticed by all who have written on the subject; it is, I believe, an important point which will help in solving the causation. Two only of the patients were women. This proportion is very much less than that in which ulcer affects the two sexes. For example, in 300 consecutive cases of duodenal ulcer operated upon 50 were women, and among 300 cases of gastric ulcer similarly treated 108 were women. Were this sex relationship to hold good with secondary ulceration, at least 8 should have been in women. In both the women operation had been carried out for chronic gastric ulcer. Both did well after removal of the offending suture. Thirteen of the ulcers were jejunal; all occurred in men and all except one after operation for duodenal ulcer.

Secondary Jejunal Ulcer.

It seems obvious that there must be some factor acting in men, and in cases of duodenal ulcer, which is not present, at any rate not to the same extent, in women and in patients with chronic gastric ulcer. This factor is, I believe, the degree of gastric acidity.

Gastric acidity is lower in women than in men and in gastric as compared with duodenal ulcer. Thus, in 50 consecutive cases of duodenal ulcer in men treated by operation the average was: free HCl 0·16 and total acidity 70; in the same number of women, 0·10 and 50. In 50 consecutive cases of chronic gastric ulcer in each sex treated by operation the average was: in men, 0·10 and 53; in women, 0·07 and 45.

Various contributory causes have been suggested from time to time. Bruising of the jejunum by clamp or the formation of a hæmatoma is undoubtedly one factor. I have noted this in 6 cases. In 3 gastric acidity was not effectually lowered by gastro-jejunostomy, and ulceration occurred in all. In the other 3 acidity was so markedly lowered that the after-history is uneventful and jejunal ulceration is not to be feared.

The following are the three cases with jejunal ulcers.

Male, aged 55. Operation for duodenal ulcer in April, 1914. Gastric acidity 0·12 and 53. I noted "a small hæmatoma formed on the jejunum just distal to the anastomosis." He made an uneventful recovery, but six months later had an attack of melæna, which recurred three times before I reoperated 14 months later. Gastric acidity was then 0·09 and 45. I found a chronic ulcer of the jejunum at the site of the hæmatoma; it had perforated and its floor was formed of transverse mesocolon. I excised the ulcer and took the opportunity of examining the suture line. The anastomosis was perfect and there was no trace of ulceration or thickening. The duodenal ulcer was healed and the jejunum, except for the ulcer, was normal. He is, and has remained, quite well.

Male, aged 39. Operation for chronic duodenal ulcer April 17th, 1912. I noted bruising distal to the anastomosis. His test-meal before operation was free HCl 0·18; total acidity, 72. He began to get pain in the lower abdomen within 18 months, and when I admitted him for investigation in June, 1914, his gastric acidity was still high—0·14 and 63. I then lost sight of him for a time, but again took him into hospital and diagnosed jejuno-colic fistula in September, 1916. His gastric acidity was then 0·09 and 35. This low acidity is the rule when jejuno-colic communication has taken place. I operated on Sept. 26th and he remains well.

The remaining patient is of interest as being the only example of jejunal ulceration I have seen following operation for chronic gastric ulcer.

C. M., a male, aged 29, came under my care in November, 1911, with a ten years' history of five attacks of pain after food and vomiting. The attacks lasted two or three months with intervals of perfect health. Test-meal, free HCl 0·11, total acidity 52. On Nov. 22nd I excised a small ulcer from the centre of the lesser curvature and did a posterior gastro-jejunostomy. I noted the formation of a jejunal hæmatoma. He left hospital for convalescent home on Dec. 5th, but returned two months later saying that the pain had recurred, but it was now to the left of the umbilicus and eased by food. Test-meal showed an increase in acidity to 0·16 and 62. I operated Feb. 14th. I opened the stomach and found the anastomosis perfect; on the anterior surface of the jejunum an inch from the opening was an ulcer which had perforated and was adherent to the mesocolon. I excised it and removed a thickened appendix. I have kept in touch with him ever since and had a letter from him from Canada last July saying he was quite well.

In none of the other cases of secondary ulcer did I notice any departure from normal at the time of operation. In 4 cases that died, post-mortem examination revealed tuberculous lesions in kidney and lungs in 3, in the other, rheumatic endocarditis. Test-meals were given in 27 patients. Both free and total acidity were raised in 12; in 10 gastric acidity was normal, but it must be remembered that a normal gastric acidity after gastro-jejunostomy is itself abnormal. Four only of these 10 were jejunal, and in 2 the ulcer communicated with the colon. Of those with lowered acidity 2 had progressed to jejuno-colic fistula, and 3 were anastomosis ulcers in which the acidity, although low, was the same as before operation.

Jejunal ulcer is found most commonly in that part of the intestine corresponding to the situation in the duodenum at which a chronic ulcer is most often met with. It suggests that the ætiology may be similar, and that it arises from failure to remove the cause of the original ulcer, or from lowering of the vitality of the intestine by bruising, in conjunction with insufficiently diminished gastric acidity. Pointing to the first suggestion is the fact that in cases recorded by Battle and others[15] and in two of mine the ulcer recurred.

Unabsorbable sutures are the cause of the gastro-jejunal or anastomosis ulcers. They may, as suggested by Garnett Wright,[16] also occasionally be responsible for the formation of a true jejunal ulcer by the irritation of a loose end.

If no unabsorbable material is used a fertile source of secondary ulceration is at once abolished. Care in the use of the jejunal clamp (personally I never use one) would also aid by removing a possible cause. If the post-operative test-meal shows a high acidity great care is necessary, and a course of medical ulcer treatment should be carried out to reduce it. This treatment should be governed by the test-meal. In every case the patient should be restrained from satisfying what is often a ravenous appetite.

I have made particular observation with regard to the structural changes that may occur in the jejunum apart from ulceration. While a dilatation of the jejunum is occasionally seen it is distinctly uncommon, and is certainly not met with in most cases of jejunal ulcer. I have notes on the condition of the jejunum in all the reoperated cases and in those in which I was able to obtain a post-mortem examination. In none were the valvulæ conniventes absent.

Paterson, in his review of the collected cases, found that in 73 per cent. symptoms began within the first two years. Among my 31 patients, in 30 symptoms began within 18 months; in only 1, an anastomosis ulcer, was the period longer, three years. While individual examples of onset at longer periods have been recorded, I think it is probable, at any rate in jejunal ulcer, that careful investigation of the history would reveal symptoms at an earlier date. The average in my cases has been, jejunal ulcer nine months, anastomosis ulcer, 12 months after operation. From the earlier records there can be no doubt that ulceration is more likely to occur after the long-loop anterior operation, for this does not so effectually reduce gastric acidity.

The prominent symptom is the onset of left-sided pain. This often has all the characteristics of that felt elsewhere before the operation; in fact, patients have said that the pain has shifted to the left, and below the umbilicus, and place their hand over the left iliac fossa in describing its position. Food relief and night waking may both be present, and the symptoms may be in attacks with periods of complete relief. I have been unable to discover any constant difference in the nature of the symptoms between the two classes of ulcer.

In all the jejunal ulcers that I have operated on the ulceration had extended through all the coats of the intestine, and the floor was formed either by the mesocolon or the colon into which perforation is common. When the floor is formed of colon, epigastric pain on defæcation may be complained of. Among 13 jejunal ulcers 5 had perforated into the colon. The prominent symptom after this accident is diarrhœa; it was present in all. It has been stated that undigested food may be found in the fæces, but this is by no means a constant feature, for in 3 cases in which this was specially looked for it was absent. In only 2 was vomiting present, and in only 1 was it fæculent. This case is of interest, as the condition was diagnosed by letter two years before operation.

In March, 1911, I operated on a male of 49 for chronic duodenal ulcer. During the first two years after operation he had attacks of pain in the lower abdomen, but not of sufficient severity to make him give up work. In November, 1914, I heard from his medical man that for a fortnight he had been having diarrhœa and vomiting, the latter at first fæcal. I replied saying the history was indicative of a jejuno-colic fistula, and that he should come in again for investigation. He got better, and I heard no more for nearly two years, when he was again seriously ill. I took him into hospital. Test-meal showed an absence of free HCl and a total acidity of 27. Bismuth meal and X ray examination did not reveal the condition. At operation I found the duodenal ulcer healed. The jejunum below the anastomosis was adherent to the transverse colon, and had perforated into it. I excised the whole anastomosis, implanted both ends of the jejunum separately into the stomach, closed the opening into the colon, and removed the appendix. In addition to the ulcer communicating with the colon there were two smaller ones immediately proximal to it. The line of anastomosis was perfect. Valvulæ conniventes were present in the jejunum, and microscopic examination revealed no abnormality other than the ulcers. He is now, and has remained, absolutely well.

Painless diarrhœa with a low gastric acidity are the symptoms of a post-operative gastro-jejuno-colic fistula. Of the five cases that have been under my care all arose in patients whom I had operated upon for chronic duodenal ulcer. One was admitted moribund 2½ years after gastro-jejunostomy. I had had him under observation for some time on account of lower abdominal pain which commenced 11 months after operation, and had seen him four months before with painless diarrhœa, and urged him to come into hospital for further treatment. At the post-mortem a jejunal ulcer was found communicating with the colon, and a smaller ulcer distal to it had perforated into the general peritoneal cavity. The duodenal ulcer had completely healed, the line of anastomosis was perfect, and the jejunum otherwise normal. The remaining cases I operated on the first died within 24 hours. The others are and have been quite well, all over three years since their second operation. Bleeding is uncommon, but in two cases of jejunal ulcer hæmatemesis and melæna were the only symptoms. Hæmorrhage also occurred in three of the anastomosis cases, but was slight and associated with pain. Vomiting is very unusual, but may be self-induced as in duodenal ulcer.

If secondary ulceration is suspected a thorough course of rest in bed and dieting should be tried, and the result checked by examination of the gastric contents. If this fails operation should be carried out on the following lines. If the ulcer is of the anastomosis type excision with removal of the offending suture; if contraction of the opening complicates it this should be re-formed. In cases of jejunal ulcer in which high acidity has persisted in spite of dealing with all disease in the abdomen the anastomosis should be excised together with the ulcer and both ends of the jejunum implanted separately into the stomach. This was done in 10 of the cases of jejunal and 5 of those of anastomosis ulcer. In the remainder the ulcer only was excised and the anastomosis re-formed or the stitch removed. Two of the jejunals developed fresh ulceration, in both excision only had been done.

One patient died in hospital of malignant disease of the thyroid eight years after I had excised a jejunal ulcer. He had remained quite well, and post-mortem examination showed the duodenal ulcer soundly healed and the scar in the jejunum hardly visible, the remainder of the jejunum being normal.

It is possible that carcinoma may follow anastomosis ulceration. I have notes of two cases which are very suggestive, although they do not definitely prove it.

In April, 1912, I operated on a man of 35 for chronic gastric ulcer. His progress was never very satisfactory, for although he was able to resume his occupation as fireman he had occasional attacks of vomiting. Four years later he came under my care again with intestinal obstruction. On admission to hospital his cæcum and transverse colon were enormously distended and I had to do a cæcostomy. I found a malignant mass in the middle of the transverse colon involving the anastomosis, but, on account of his condition, was unable to make as thorough an examination as I should have liked. I removed a small portion of the growth for sections. This showed spheroidal-celled carcinoma of the type arising in the stomach.

The other patient was operated upon by Mr. W. F. Brook at Swansea, to whose kindness I am indebted for the notes.

In December, 1913, I operated on a man of 54 with chronic duodenal ulcer. He remained perfectly well for three and a half years. On writing again last year I heard from his daughter that he had died after an operation which had been carried out for trouble with his bowels of six months' duration. Mr. Brook operated on account of subacute intestinal obstruction due to a malignant mass in the transverse colon, which involved the gastro-jejunostomy opening. Further investigation was, unfortunately, impossible.

In both patients, following a gastro-jejunostomy, a malignant mass was found in a part of the transverse colon, which is very rarely the seat of carcinoma. In both it involved the anastomosis, and it seems more than probable that it arose in the gastric mucous membrane from an anastomosis ulcer.

THE RESULTS OF OPERATIVE TREATMENT OF CHRONIC DUODENAL ULCER.

We must now pass to the consideration of the results of operative treatment of chronic duodenal ulcer. The cases under review, those to the end of December, 1917, number 389. In 2 of these the ulcer was directly involving the stomach, and in 7 a separate ulcer was present on the lesser curvature. These figures include 35 in whom the operation was carried out on account of hæmorrhage, but exclude those operated upon for acute perforation. There were 9 deaths, 3 being among the 35 operated on directly for hæmorrhage due to continuation of the bleeding, pulmonary embolism, and in the third the abdominal wall gave way 12 days after operation and the patient died of pulmonary complications after resuturing. Of the others, 2 died of broncho-pneumonia, 1 of pulmonary embolism, 1 after a second operation for regurgitant vomiting, 1 from hæmatemesis, and 1, a patient with a dilated stomach, died six days after operation and no cause could be discovered post mortem. 379 were treated by gastro-jejunostomy, with or without inversion of the ulcer, and in 2 the ulcer was excised in addition for diagnostic purposes. In one patient from whom I removed a calcified hydatid cyst of liver I excised a small ulcer of the anterior wall without doing a gastro-jejunostomy; she remains well over four years later. In 5 cases partial gastrectomy with removal of the affected part of the duodenum was carried out and in 2 a double gastro-jejunostomy. All these patients remained perfectly well.

The Healing of the Ulcer.

I have had the opportunity of examining the site of the ulcer post mortem in 8 cases—respectively 6, 9, and 18 days, 15 months, and 3 (2 cases), 8, and 9 years later. In all except the first the ulcer had healed; this was a patient of 48 with a history extending over 13 years, during the last two of which there had been vomiting of the dilated stomach type. He was extremely ill, with an enormously dilated stomach. At operation I found a mass adherent to the under surface of the liver and gall-bladder. I noted "evidently a chronic duodenal ulcer which has perforated." I did a posterior gastro-jejunostomy. He died on the sixth day without further vomiting, apparently from exhaustion. At the post-mortem no cause for death could be discovered. There was a chronic ulcer of the anterior surface of the first part of the duodenum, which had perforated and was adherent to the gall-bladder, which closed the perforation and formed the floor of the ulcer. At subsequent operation I have been able to investigate the condition of the duodenum in 21 of my patients. The ulcer had healed in all at 2, 6 (2 cases), 7, 8, 11 (2 cases) months, 1 (3 cases), 2 (2 cases), 3 (4 cases), 6 (4 cases), and 10 years after gastro-jejunostomy.

There can be no doubt that gastro-jejunostomy is a curative operation for chronic duodenal ulcer, and that symptoms which may arise later, except when the ulcer has eroded the pancreas deeply and is hence unsuitable for treatment by gastro-jejunostomy alone, result from mechanical or ulcerative complications in connexion with the anastomosis.

Condition of Patients after Two Years.

Of the 389 cases, I have been able to trace 348 up to the present time or death more than two years after operation. 318 are, and have, remained perfectly well, including all the partial gastrectomies and double gastro-jejunostomies. I have found no difference in the result in the cases in which the ulcer was treated by inversion in addition to gastro-jejunostomy. Two died of causes unconnected with the operation before the expiration of the two years, and 30 could not be traced for this time, but were well when last heard of.

Nineteen developed secondary ulceration, one of whom, already mentioned, died shortly after readmission; the remainder were treated by operation. Ten were jejunal. Of the 18 operated on, four died, one after a second operation for an anastomosis ulcer; I had been unable to remove all the stitch at the first operation. Of the survivors, one died eight years after his second operation, remaining quite well up to this time; the others are well at 9, 7, 6, 5, 4, 3 (4 cases) years later; one is improved, but not quite well; one I have lost sight of; and two have been done under two years, but are well.

No jejunal ulcer has arisen in any uncomplicated case that I have operated upon since February, 1914, and no anastomosis ulcer since I gave up the use of an unabsorbable suture for the outer layer. Most of my cases occurred in patients operated upon in 1911, 1912, and 1913. Since that date I have made the anastomosis nearer the cardiac end of the stomach, and so obtained a greater reduction in gastric acidity.

Only one jejunal ulcer has, as far as I am aware, developed among the cases operated upon during the last five years. This was in the patient mentioned under regurgitant vomiting, whom I surgically treated in January, 1918, and has since had to be operated upon on two occasions for jejunal ulcer.

Among the cases not quite well is one, the last patient in whom I used a thread stitch, who may possibly have an anastomosis ulcer. The complaints of the remainder are few, and with the exception of the one just mentioned express themselves as better because of the operation, although not absolutely well. Three of these have become quite well after a few months' discomfort, the two I have previously mentioned and the following, which is a good illustration and very suggestive of the escape of the offending suture.

I operated on J. P., a male, aged 46, on March 11th, 1913, using catgut for the inner and thread for the outer layer of sutures. He gave a typical history extending over 16 years. His test-meal showed free HCl 0·27 and acidity 100. Four months after operation he began to complain of lower abdominal pain and five months later I had him under observation and found his gastric acidity reduced to 0·07 and 33. He had attacks of pain for nearly two years, in the last of which he had melæna. He has now been absolutely well for over four years. Before his operation his longest period of relief was three months.

THE POSSIBLE DEVELOPMENT OF CARCINOMA IN A SIMPLE ULCER.

The question of the possible development of carcinoma in a simple ulcer must now be briefly considered. Malignant disease of the first part of the duodenum is unusual. Jefferson,[17] in publishing a case of his own, was able to collect 30 in which there was a possibility that the condition arose in a pre-existing simple ulcer. He states "several of these are very doubtful." I agree with him.

I have operated on 9 cases of carcinoma of the duodenum. In 2 it was situated in the third part close to the duodeno-jejunal flexure, in 6 in the second part, and in 1 only was it supra-ampullary and occupying the usual situation of a simple ulcer.

On April 8th, 1913, I operated on a male, aged 40, who was sent to me on account of gastric dilatation. He had suffered from indigestion "all his life." For five weeks before I saw him vomiting of the dilated stomach type had been present. He was very wasted, with a large stomach. Test-meal showed absence of free HCl and a total acidity of 24. I found a hard constricting mass in the first part of the duodenum with scattered whitish nodules. I removed one for sections and did a posterior gastro-jejunostomy. Microscopic examination revealed columnar-celled carcinoma, and he died in December, 1914, with painless jaundice after over a year's perfect comfort.

I know of no patient developing malignant disease of the duodenum after operation, but there is one doubtful case. In April, 1912, I operated on a male of 49 for chronic duodenal ulcer. He remained in perfect health for 6½ years and then died after 14 days' illness. Unfortunately I did not hear about it until some months later. I had a letter from his wife in which she said: "An incision was made and a growth found on the backbone, also ulcer." I have repeatedly tried to get into touch with the medical man who is supposed to have done the post mortem, but have failed to obtain any information. I have included him among the failures, but it is quite possible that the condition had nothing to do with his original disease.

I have previously[18] briefly recorded two cases in which ulcers of the duodenum were found to be involving the stomach, and at a second operation I found malignant disease of that viscus, the duodenal ulcer having healed. The following are the details of the cases.

On May 31st, 1912, I operated on a man of 54 with six years' history suggestive of duodenal ulcer followed by symptoms of dilated stomach. Operation revealed a large dilated stomach, due to an ulcer of the anterior and upper surface of the first part of the duodenum extending on to the lesser curvature of the stomach. After gastro-jejunostomy he remained perfectly well for 18 months, and then began to complain of abdominal pain and a mass developed in the epigastric region. At the second operation, 23 months after the first, I found the duodenal ulcer healed but diffuse carcinoma of the stomach.

On Sept. 3rd, 1912, I operated on a woman of 45 with a typical history of duodenal ulcer of seven years' duration. I found a markedly indurated ulcer of the anterior surface of the first part of the duodenum extending on to the stomach. She remained well for a year after gastro-jejunostomy, and then began to complain of abdominal discomfort. I operated again in May, 1914. The duodenal ulcer had healed, but the pyloric end of the stomach was much thickened, and there were enlarged coronary and subpyloric glands. I did a partial gastrectomy. On examining the specimen there was an indurated ulcer on the gastric side of the pylorus, encircling the stomach except on its anterior surface. Microscopic examination showed it to be a simple ulcer with carcinoma starting at its cardiac edge. All the lymphatic glands were infected. She lived in comfort for over a year, and died with an enlarged liver and jaundice 17 months after operation. Her medical man, who watched her throughout, in his letter describing the end, said "the most noteworthy point was the relief given by the operation."

Since these cases I have always done a partial gastrectomy when this complication is present.

THE RESULT OF THE SURGICAL TREATMENT OF CHRONIC DUODENAL ULCER.

The result of the operative treatment of chronic duodenal ulcer rivals that of any other major operation. With care during operation and with the after-treatment jejunal ulcer should become almost, if not quite, unknown. Gastro-jejunostomy is the operation of choice in all except those in which the ulcer is involving the stomach or deeply eroding the pancreas. Both should be treated by excision. Among my cases "not quite well" are three in whom this latter condition was present. The successes more than two years after operation are a little over 80 per cent. of those operated upon. This is considering all who cannot be traced or who died before the two-year period of other causes, 32, as failures. These figures agree very closely with those obtained in a similar way by Sir Berkeley Moynihan,[19] 82·78 per cent. out of 305 operated upon, when we consider that 22 of these could not be traced or died of other causes, and some were reported before the lapse of two years.

If we take the successes among those traced, and there is no reason to consider that those who have changed their addresses or died of influenza or wounds would in any way alter them, it is over 90 per cent. I believe that the treatment of chronic duodenal ulcer on the lines laid down will result in 95 per cent. cures.

THE RESULTS OF THE SURGICAL TREATMENT OF CHRONIC GASTRIC ULCER.

The results of the surgical treatment of chronic gastric ulcer cannot be dealt with as simply as those of chronic duodenal. I wrote in 1914: "The operation to be performed in any individual case of chronic gastric ulcer can only be decided after the abdomen is opened." I again want to preface my remarks in this way. I also hope to be able to show what I then stated: "Simple chronic gastric ulcers will heal as the result of gastro-jejunostomy correctly performed unless they are adherent and have perforated, their floor being formed of pancreas or liver." Owing to failure of gastro-jejunostomy to cure the type of ulcer last mentioned I have used it with diminishing frequency during the last seven years. For example, in 100 consecutive cases operated upon before December, 1912, gastro-jejunostomy alone was done in 90, combined with excision of the ulcer in 8; partial gastrectomy was done in 2 cases only. In 100 consecutive cases before December, 1919, 50 were treated by gastro-jejunostomy alone, 2 by this operation combined with excision, and 48 by partial gastrectomy. Up to this time I had carried out partial gastrectomy for simple ulcer in 101 cases with 9 deaths. It is fair to say that the ulcers operated upon during this period were much more extensive and included some that I should previously have considered inoperable.

The cases of chronic gastric ulcer operated upon up to December, 1917, number 310 with a mortality of 11. These figures include all ulcers treated by operation, except for acute perforation. The operations are as follows:—

Excision alone.. ...	9 cases. 1 death from subphrenic abscess.
Partial gastrectomy	52 cases. 4 deaths. Acute dilatation of stomach, pulmonary embolism, pneumonia, no cause found post-mortem.
Gastro-jejunostomy and excision ...	25 cases. 1 death from urethral stricture and pyelitis a month later.
Gastro-jejunostomy alone	224 cases. 5 deaths. 3 from pulmonary complications, 1 from leakage 10 days after operation for hæmatemesis, and 1 from hæmatemesis.

Results of Cases of Excision and of Partial Gastrectomy.

All the partial gastrectomies except two are quite well, and none complain of any discomfort from the smallness of the stomach. They eat ordinary food in the usual quantity. One patient after three years says: "Intimate friends regard me somewhat as an astonishing freak. The fact remains that I can manage and mix diets as few of them dare to do." One of the patients operated on nearly seven years has been able to take ordinary diet ever since, and in spite of being over 60 was able to rough it on the continent during the war. The immediate post-operative recovery of these patients is astonishing, and the sisters of my wards say they get even less discomfort than that experienced as a rule after gastro-jejunostomy. Of the two not quite well, one complains of occasional vomiting and one of occasional indigestion; neither has been of sufficient severity for me to obtain their permission for further investigation. I have not yet had the opportunity of examining any of the cases either post mortem or at second operation at remote periods, and none have developed any symptoms suggestive of secondary ulceration.

Of the 8 survivors of excision only 2 have remained well, one 7 and the other 2½ years later. In the latter the operation was carried out for hæmatemesis and nothing more was justifiable. In 5 I have had to reoperate, symptoms having recurred within 18 months. I performed gastro-jejunostomy 6, 5½, 3½ (2) years ago and all remain well. In the fifth diffuse peritoneal adhesions prevented anything but excision at the original operation; my second operation was no more successful and she is still unrelieved.

Results of Cases of Combined Gastro-jejunostomy and Excision.

I have been able to trace 22 of those treated by excision combined with gastro-jejunostomy; all except 2 are quite well. A man of 62 complains of pain in his chest on lifting, but has lost all his gastric troubles, and a woman of 53, who speaks of her ill-health; but I have been unable to obtain any definite complaint of gastric symptoms. In none of these has malignant disease subsequently developed.

Results of Cases of Gastro-jejunostomy Alone.

Of the 219 survivors of those treated by gastro-jejunostomy alone I have been able to keep 187 under observation for over two years; 162 have remained perfectly well. I have found no difference in the result in those in whom the ulcer was "inverted." In no case was pyloric exclusion practised; 24 died from causes unconnected with the operation at over 11 (2), 9 (2), 7 (2), 6 (3), 5 (2), 4 (3), 3 (4), 2 (5), and 1 year later after remaining perfectly well. In 1907[20] I recorded what I believe to be the first instance in which the healing of a chronic gastric ulcer as the result of gastro-jejunostomy was verified by post-mortem examination. Since that date I have been able to obtain post-mortem examinations in 8 from 2 to 9 years after operation, and found the ulcer soundly healed and the anastomosis perfect, without any trace of thickening or contraction. In addition I have had the opportunity of examining the site of the ulcer at subsequent operation in 13 patients, 2, 3, and 4 weeks, 3 and 18 months, 2 (3), 3 (2), 6 (3), and 7 years later: the ulcer had healed in all.

Twenty-five have had further symptoms. Nine of these were patients in whom the ulcer had perforated and was adherent to pancreas or liver, cases I now invariably treat by partial gastrectomy. One of this group died 18 months later of hæmatemesis. As the result of subsequent excision of the ulcer 5 have been in perfect health for over three years. In 4 symptoms were due to secondary ulceration, but in only 1 was it jejunal. All were treated by operation. One died as the result; post-mortem examination revealed tuberculosis of the right kidney and bladder; the gastric ulcer had healed and the operation area was perfect. One died of influenza after 3½ years of perfect health and the remaining 2 are well seven and four years later.

Occasional vomiting is a more common complication than after gastro-jejunostomy for duodenal ulcer. This is due to the position of the opening depending on the position of the ulcer; the anastomosis may have to be much farther to the left than ideal. In two it was so persistent that further operation was carried out two and three years later.

Three died of carcinoma of the stomach seven, five, and four years after operation. The following are brief notes:—

In June, 1910, after a gastric history extending over 30 years, I operated on a male of 53. I found a large chronic ulcer on the lesser curvature close to the pylorus, and did a posterior gastro-jejunostomy. I heard each year until 1917 that he was quite well. On writing in March I heard that he had just died of hæmatemesis with an epigastric tumour.

In March, 1911, I operated on a male of 58. My notes say: "I found a chronic ulcer at the cardiac end of the lesser curvature involving the posterior surface and adherent to the pancreas. I should have liked to excise it, as I was not certain of its innocence, but his condition would not permit." I heard from him as "quite well" in March, 1912, May, 1913, and July, 1914. In March, 1915, he came to see me, saying that he had been having abdominal pain for four months. I found an obvious malignant mass in the upper abdomen, and he died a few weeks later.

I operated upon a man of 57 in September, 1912, for a chronic ulcer in the middle of the lesser curvature. I heard from him in June, 1914, as quite well, but then lost sight of him, but he came to see me in January, 1917, saying he had been well until two or three months previously, when he began to get abdominal discomfort. I found a small epigastric tumour and a mass of hard glands in the left supra-clavicular region. He died two months later.

Although post-mortem evidence is unfortunately lacking, I have no doubt that these are instances of carcinoma of stomach, but whether arising at the seat of the ulcer it is, of course, impossible to say. All the ulcers were of the type I now treat by partial gastrectomy.

The following is of interest, for if the original operation had been for gastric instead of duodenal ulcer and perforation had not occurred the same difficulty would have arisen.

In September, 1906, I operated on a man of 32 for profuse hæmorrhage from a chronic duodenal ulcer. He remained perfectly well until January, 1910, when after a fortnight of vague epigastric pain he was suddenly seized with the typical symptoms of perforation. I operated on the diagnosis of perforated jejunal ulcer. The anastomosis was perfect and the duodenal ulcer healed, but he had a small carcinoma of the anterior wall of the stomach which had perforated.

Among 135 ulcers removed up to the end of December, 1919, on the diagnosis of simple, the ulcer to the naked eye showing none of the signs of malignancy, in 6 carcinoma starting in the edge of a simple ulcer was discovered on microscopic examination. On the other hand, 14 out of 57 operated upon for carcinoma, partial gastrectomy being performed, there was definite microscopic evidence that the malignant disease started in the edge of a simple chronic ulcer. These facts have an important bearing on operation for chronic gastric ulcer, and should influence us in our choice of partial gastrectomy.

Hour-glass stomach presents many features of clinical interest, but does not call for any departure from the rules laid down for the treatment of ulcer without this complication.

Up to the end of January, 1920, I had operated upon 80 cases with 4 deaths. The procedures adopted were:—

Partial gastrectomy	49 cases, 3 deaths.
Single gastro-jejunostomy ...	26 cases, 1 death.
Double gastro-jejunostomy ...	5 cases.

All those operated upon over two years are well with one exception, and in this patient the complaint is of occasional discomfort only.

I do not think it can be doubted that the majority of the cases of chronic gastric ulcer will heal as the result of gastro-jejunostomy alone. Partial gastrectomy, however, has much in its favour. It is the only efficient treatment for all chronic perforated ulcers, and as it is impossible to decide if an indurated ulcer is malignant or if its scar will many years later take on malignant change it should become the treatment for all except small free ulcers.

At the end of 1911 I began to carry out partial gastrectomy by what I believed to be the original method, closing the cut end of the duodenum and uniting the jejunum directly to the divided cardiac end of the stomach. I introduced this to the Mayo Clinic early in 1914,[21] who have since popularised it, and it has become known as the Polya-Mayo operation.[22] I have found it a most satisfactory procedure, and although the death-rate is at present higher than that of gastro-enterostomy I believe that it will be reduced to 5 per cent.

SUMMARY OF GASTRIC ULCER CASES.

To summarise the results. Of the 310 cases, 220 have remained perfectly well for more than two years or died at a later date of other causes after having had no further gastric trouble. This is 75 per cent. of those operated upon. Of those traced it is over 80 per cent., and the remarks I made with regard to duodenal ulcer apply here. These figures are not as good as those of chronic duodenal ulcer operated upon during the same period, but it must be remembered that they include cases treated by excision alone, which failed to relieve in 6 out of 8, and also posterior adherent ulcer, which I now treat by partial gastrectomy and which were either relieved only or needed a second operation to bring to a successful issue and are not included among the "cures."

CONCLUSION.

In conclusion, I should like to recapitulate the points I have tried to bring out. While gastro-jejunostomy combined with general abdominal exploration and dealing with other diseased organs is curative in the majority of cases of chronic duodenal ulcer, each must be studied, and those eroding the pancreas or spreading to the stomach removed. Gastric ulcers which have perforated and are adherent to neighbouring organs, indurated ulcers on the lesser curvature, and all in which there is any suspicion of malignancy must be treated by partial gastrectomy. I believe that gastro-jejunostomy for chronic gastric ulcer will become the less frequent operation. Symptoms arising later if the correct operative procedure has been adopted are due to mechanical or ulcerative changes in the region of the anastomosis, both prevented by careful technique, in the majority of cases, and becoming less frequent as individual experience ripens.

I wish to thank all those colleagues in the medical profession, too numerous to mention individually, who have readily assisted in my inquiries, and have so helped to trace the result in patients who would otherwise have been lost.

THE SIGNIFICANCE OF ARNETH'S REACTION,

WITH PARTICULAR REFERENCE TO PULMONARY TUBERCULOSIS.

BY H. A. TREADGOLD, M.D. LOND.,
SQUADRON LEADER, ROYAL AIR FORCE MEDICAL SERVICE; AND FORMERLY ASSISTANT SUPERINTENDENT TO THE BROMPTON CHEST HOSPITAL LABORATORIES.

(*From the Laboratories, Brompton Hospital.*)

ARNETH,[1] in 1904, first drew attention to the fact that the number of the lobes of nuclei in neutrophile leucocytes, although constant in health, was altered considerably in certain infectious diseases. He divided neutrophile leucocytes into five classes, according to the number of nuclei they contained, and further divided these five classes into three, four, or more sub-classes dependent on the shape of the nuclei. He attached most importance to changes occurring in Classes I. and II.—i.e., in those leucocytes containing one or two subdivisions of the nucleus, and his index was the sum of these two found in counting 100 such cells. The usual change observed was a well-marked increase of Classes I. and II. in infectious disease, which he called a shift to the left. In pulmonary tuberculosis he claimed that: (1) the shift to the left was in proportion to the extent of the disease; (2) as the patient improved, so the index moved more nearly to the normal; (3) unless the index was normal, no case could be regarded as really cured. Many papers have since been written on the subject, and almost all of these are collected by A. von Bonsdorff,[2] who refers to 160 papers in his bibliography. In a lengthy treatise he agrees in the main with Arneth's conclusions. In addition to the shift to the left, a shift to the right has been less frequently described. Schilling (Torgau)[3] describes this as occurring in some infectious diseases, including "pure tuberculosis"; a shift to the left being found in general sepsis and mixed tuberculous infections, and to the extreme left in the final stages of leukæmias and septicæmias. No change in the index occurred in new growth, pernicious anæmia, and chlorosis. More recently Knapp[4] has found a shift to the right, occurring rather indefinitely in some cases to syphilis, dysentery, and ankylostomiasis. In leprosy 12 cases out of 15 examined showed a definite right shift and 3 a left shift. This shift to the right has been ignored by the great majority of writers on the subject, possibly on account of its infrequent occurrence. Various papers written from time to time on Arneth's reaction in pulmonary tuberculosis make no mention of the right shift, an omission possibly due to the small numbers of blood films examined in most cases. It is not proposed to include in the present paper a complete résumé of previous work on the subject, as this has already been done by Von Bonsdorf. Papers published since his review include those by Rayevski[5] and Kramer,[6] both of whom agree that a left shift denotes a grave prognosis in pulmonary tuberculosis, and Cooke,[7] who claims the test as one of great value in the same disease in prognosis, diagnosis, and as a guide to treatment. Chamberlain and Vedder,[8] Breinl and Priestley,[9] and Macfie[10] all describe a left shift among healthy whites in tropical climates, the latter regarding it as due to abortive inoculation with malarial parasites by infected mosquitoes.

The present paper was commenced in 1913, and was approaching completion at the outbreak of the war. It has been found impracticable to proceed any farther with it owing to the lapse of time that has occurred, and it is not nearly as complete in consequence as was intended originally.

Determination of Normal Count.

Arneth himself expressed the reaction as the sum of Classes I. and II. in 100 cells; others have added half the number of Class III. to these figures. The most convenient way of expressing it is that of v. Bonsdorff, who adds all the lobes of the nuclei of the five classes together. Thus, Arneth's original normal count, which was

5 (Class I.) ... 35 (II.) ... 41 (III.) ... 17 (IV.) ... 2 (V.)

can be expressed as 40, 60·5, or 276—i.e.,

$$(5 \times 1) + (35 \times 2) + (41 \times 3) + (17 \times 4) + (2 \times 5).$$

v. Bonsdorff's normals are farther to the left than this, and further, he gives different normals for men and women, e.g.:—

Class.	I.	II.	III.	IV.	V.	
Men ...	... 8	... 38·4	... 40·2	... 12·4	... 1·0	= 260
Women	... 12·5	... 44·85	... 33·55	... 8·35	... 0·75	= 240

The extreme limits of the normal count he places between 220 and 290, and in pulmonary tuberculosis between 285 and 125. It is inevitable that different observers should disagree to a certain extent as to what constitutes a normal count, as nuclei joined together by a bridge count as one, and if only separated by a thread, as two. In the present inquiry, after counting over 50 blood films, it was found that the normals became constant within 5 per cent., and that the same film could be placed in a separate series from time to time, and the result found to be always within this margin, such normals more closely coinciding with v. Bonsdorff than Arneth. A definite difference was found between men and women, though not as great as v. Bonsdorff describes. Control figures were as follows:—

I.	II.	III.	IV.	V.		I.	II.	III.	IV.	V.	—
Women.						*Men.*					
11	34	48	7	0	= 251	9	38	42	10	1	= 256
12	49	36	2	1	= 231	9	36	47	8	0	= 254
13	46	34	7	0	= 235	9	47	49	5	0	= 240
13	41	38	7	1	= 242	8	39	40	12	1	= 259
13	42	37	7	1	= 241	12	38	36	13	1	= 254
Average.						*Average.*					
12·4	42·4	38·6	6·0	0·6	240	9·4	39·6	40·8	9·6	0·6	252·6
Author's blood taken at 14 days' periods.											
12	39	38	10	1	= 249	12	42	38	7	1	= 243
11	43	36	9	1	= 256	11	44	35	9	1	= 247

Normal limits were arbitrarily fixed as 210 to 270 for women and 220 to 280 for men.

Technique Employed.

The technique employed was as follows:—Four cover-glass films were prepared from each case. Leishman's stain being used. The best of these was then taken and a hundred neutrophile leucocytes counted. The films were numbered by an independent observer, who kept the key till counts were complete.

Preliminary Observations in Various Pathogenic Conditions.

A series of blood films were counted in various pathogenic conditions. Results were as shown in Table A.

These results, agreeing as they do with those of previous workers, reveal a definite shift to the left, its amount appearing to depend upon the severity or extent of the infectious process.

TABLE A.

—	Disease.	Arneth.					
		I.	II.	III.	IV.	V.	—
1	Acute pyæmia	68	30	2	0	0	= 134
2	Uræmia with hypostatic pneumonia	60	33	7	0	0	= 147
3	Severe and extensive septic burn involving left arm and neck ...	58	33	9	0	0	= 151
4	Appendix abscess recently opened. Some peritonitis	56	35	9	0	0	= 153

13	Chronic bronchitis and asthma ...	17	47	28	8	0	= 227
14	Pernicious anæmia (chronic) ...	12	44	32	12	0	= 244

Observations on 30 Cases of Pulmonary Tuberculosis.

A series of 30 cases representative of various stages of pulmonary tuberculosis were then carefully selected; all had tubercle bacilli present in the sputum. All cases were examined on at least three occasions over a minimum period of two months. The average time each case remained under investigation was 3·8 months, and the average examinations made were 4·15 per case, a total of 124 blood films being counted. Analysis of these cases showed that 29 had a more or less marked shift to the left, and one a definite and continuous shift to the right. There were 10 deaths, 10 cases

TABLE B.—*Deaths, 9.*

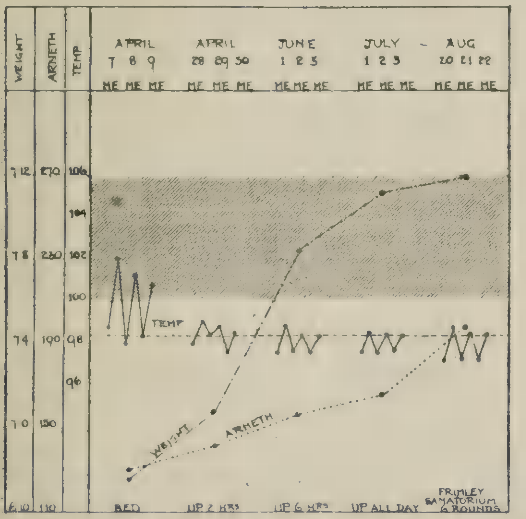
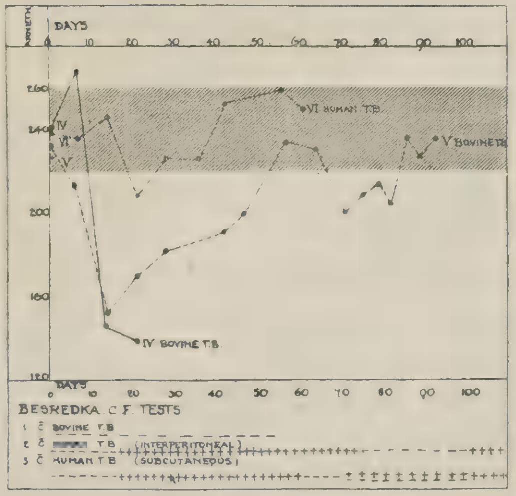
4



CASE 24.—Class III. type.

6



Rabbit experiments.

discharged unimproved after treatment, and 10 cases definitely improved. Further analysing the 29 cases with left shift by averaging the first, middle, and last count in these three classes, results were as given in Table B. (Details of nuclei in each class are omitted for reasons of space.)

These figures show that Class I. has a marked and progressive left shift, and that Class II. is fairly constant and intermediate between Classes I. and III., the latter of which is distinctly higher than the other two and shows a progressive shift towards the normal. There are no normal counts in Classes I. and II., and only one case in Class III. The greatest and least left shifts in the last blood films taken before death were 105 and 162 respectively; in Class II. the extreme figures met with were 138 and 214, and in Class III. 129 and 224.

Details of the only case showing a right shift and typical cases representative of Classes I., II., and III. are as follows:—

CASE 27. Showing right shift (Chart 1).—Female, aged 60. Chronic fibroid lung of long standing, with extensive cavitation and heart drawn over; bronchitis and emphysema; slight resting febrile; very little sputum. (Table C.)

TABLE C.

—	I.	II.	III.	IV.	V.	—	Weight.
							st. lb.
Jan. 21st	3	26	37	23	11	= 313	7 9
Feb. 4th	8	27	46	16	3	= 279	7 8½
March 5th. Losing weight steadily	8	25	45	19	3	= 284	6 11
March 30th. Still losing weight and doing badly ...	5	23	45	23	4	= 298	6 10½
April 16th	6	24	44	21	5	= 290	6 10

April 30th, sent out to home for incurables. June 1st, death.

CASE 6 (Class I. type. Chart 2).—Three lobes involved on admission, spreading to five before death. Resting febrile acute. Weight unobtainable. (Table D.)

TABLE D.

—	I.	II.	III.	IV.	V.	—
Jan. 9th. Acute enteritis...	74	24	2	0	0	= 128
Jan. 21st. Enteritis better, but losing ground	50	40	9	1	0	= 161
Feb. 7th	70	27	3	0	0	= 133
Feb. 9th	61	35	4	0	0	= 143
Feb. 11th	76	22	2	0	0	= 126
Feb. 18th	69	23	8	0	0	= 139

March 1st, death.

CASE 3. (Class II. type. Chart 3).—12 months' history. Involvement of five lobes. Ambulant, afebrile, fair appetite, and general condition good, large amount of sputum apparently largely bronchial in nature. (Table E.)

TABLE E.

—	I.	II.	III.	IV.	V.	—	Weight.
							st. lb.
Jan. 29th	57	34	9	0	0	= 152	8 13½
Jan. 21st	57	34	9	0	0	= 152	8 12
Jan. 29th. Under terpezone treatment. Has lost 2 lb. in last 14 days, and become resting febrile	59	32	9	0	0	= 150	8 10
Feb. 18th. Has become resting afebrile. (Up 2 hours.)	49	38	12	1	0	= 165	8 8½
March 17th. Still losing weight; in bed	55	33	12	0	0	= 157	8 4
April 17th. Still losing weight; slowly up, 2 hours. Still good appetite, but pulse remains steadily above 100	56	35	8	1	0	= 154	8 3½
May 20th. Still losing weight	45	36	19	0	0	= 174	8 2
June 12th. To be discharged unimproved. Slight ambulant febrile ...	58	36	6	0	0	= 148	—

CASE 24 (Class III. type, Chart 4).—Early involvement of both upper apices; three months' history. Marked resting febrile slowly coming down on absolute rest. Bad appetite. (Table F.)

TABLE F.

—	I.	II	III.	IV.	V.	—	Weight.

June 2nd. Already improved; ambulant afebrile. Up 6 hours. ...	51	42	7	0	0	= 156	7 8¼
July 2nd. Has gained 13½ lb. since admission. Up all day	46	44	10	0	0	= 164	7 11¼
August 21st. Discharged to Frimley July 21st. Now on 6 rounds; doing well ...	27	44	27	2	0	= 204	7 12

Although a study of these figures bears out, to some extent, claims made by other observers that the more marked the left shift the worse the prognosis, it also reveals the great danger of drawing any conclusions from single Arneth examinations. Case 24 is a striking illustration of this. Again, two consecutive examinations showing a marked rise in the Arneth count are not necessarily indicative of the improvement in the lung condition of the patient (vide Case 6). The reason of the right shift in Case 27 was altogether obscure at this stage.

In view of the fact that the average tuberculous sputum usually contains considerable numbers of well-preserved neutrophile leucocytes, films of tuberculous sputa were stained by Unna's polychrome-blue method, and the results contrasted with blood films of the same patients taken the preceding day. The first ten cases examined proved remarkably constant, the maximum variation in the count between the sputum and blood films being in no case more than 5 per cent. Further investigation showed, however, that the leucocytes of many perfectly fresh tuberculous sputa were disintegrated and impossible to count and the method was abandoned.

TABLE G.—*Old Cases of "Clinical Arrest."*

No. of case.	Year discharged.	—	I.	II.	III.	IV.	V.	—
1	1910	Quite well until one year ago, when cough and slight hæmoptysis occurred. Has since lost 12 lb. in weight, but is on full work as packing-case maker	45	35	18	2	0	=177
2	1911	"Perfectly well." No recent loss of weight on full work	14	52	31	3	0	=223
3	1912	"Feels quite well." On full work as night porter	18	43	35	4	0	=225
4	,,	"Perfectly well." On full work as policeman	14	52	30	4	0	=224
5	1913	"Perfectly fit." No loss of weight...	25	43	28	4	0	=211
6	,,	"Perfectly fit." No loss of weight. Tram-driver ...	12	43	39	6	0	=239
7	,,	Has lost 6 lb. in last 6 months, but feels well ...	45	36	18	1	0	=175
8	,,	"Perfectly fit." At full work.	15	52	28	5	0	=223
9	1914	Discharged from Frimley under two months. Is running evening temp. to 100°, had slight hæmoptysis week previous to examination	30	55	13	2	0	=187
10	,,	"Perfectly fit." No loss of weight; at full work	12	37	40	10	1	=251

Regarding Cases 1, 7, and 9 as probable relapses and the remainder "clinically arrested," the average Arneths of the two classes are 179·6 and 228 respectively.

Observations on Old Cases of "Clinical Arrest."

An attempt was next made to study Arneth counts in cases previously discharged from Frimley Sanatorium as "clinically arrested." Considerable difficulty was experienced in following these up and only ten could be obtained. Particulars are as given in Table G.

Conclusions.

(I.) That a shift to the left is usually present in cases of active pulmonary tuberculosis, the degree of shift being most marked, and generally progressive, in dying cases. It is less marked and is apt to remain fairly constant in cases which do not improve under treatment, while cases definitely improving usually show the least degree of shift, and this becomes progressively less as improvement continues.

(II.) While this is true as a general rule, there are exceptions which do not conform, notably Case 27 (right shift) and Cases 24, 4, 12, 13, 29.

(III.) It is inadvisable and dangerous to draw any conclusions from single Arneth examinations. At least three extending over a period of some weeks should be made. Evidence obtained in this way may often prove of help as a key to the progress of the patient.

(IV.) A constant and marked left shift in early suspected cases of pulmonary tuberculosis, where other sources of infection can be excluded, is presumptive evidence of active mischief.

(V.) A left shift under 200 in old cases of "clinical arrest" is suggestive of recurrence and calls for minute and careful re-examination.

Animal Experiments.

A series of experiments were next undertaken on rabbits and guinea-pigs, infected with living tubercle bacilli, and blood films made at regular intervals in order to follow out the disease from beginning to finish.

(A) *Experiments on Guinea-pigs.*

Controls showed that healthy guinea-pigs had a constant Arneth count in the region of 267. Limits of normal were fixed between 240–290. Figures were as follows:—

Controls—Guinea-pig.	I.	II.	III.	IV.	V.	—
I.	16	25	41	14	4	=265
II.	14	47	41	14	4	=267
III.	10	32	43	11	4	=267
IV.	10	28	41	17	4	=277
V.	12	32	42	11	3	=259
Average ...	12·4	28·8	41·6	13·4	3·8	=267

EXPERIMENT I.—*Guinea-pig No. 1.*

—	I.	II.	III.	IV.	V.	—	Weight in grammes.
May 26th. 5 c.cm. emulsion of T.B. sputum injected intraperitoneally	10	28	41	17	4	= 277	450
May 29th	5	26	36	24	9	= 306	410
June 2nd	13	25	40	16	6	= 277	450
June 5th. Marked leucocytosis	3	24	38	28	7	= 312	450
June 9th	24	45	25	5	1	= 214	410
June 12th. 12 A.M. ½ m.g. old tuberculin injected subcutaneously right thigh	39	48	13	0	0	= 174	390
6 P.M.	36	51	13	0	0		

8 P.M., Death.

Marked anaphylactic shock immediately after injection, but temporary recovery after two minutes; almost moribund 6 P.M. (O.T. was injected in order to determine its effect, if any, on the Arneth count, but death supervened too soon for further blood examinations to be made.)

Post-mortem.—Miliary tuberculosis of liver and spleen which were both much enlarged, especially the latter. Lungs congested but all other organs apparently normal. Lungs on section showed extreme engorgement and marked enlargement of cells of bronchial mucous membrane, many of which were desquamated so as almost to block all the bronchial lumina.

EXPERIMENT II.—*Guinea-pig No. 2.*

June 30th	14	36	40	10	1	= 251	700
July 14th	12	35	39	12	2	= 257	720
August 19th ...	16	21	39	13	1	= 253	730

Killed the same day. Post mortem, all organs normal.

Chart 5 shows the progress of the Arneth counts in each case.

In Experiment I. there is a sharp fluctuating right shift up to the 10th day, followed by a very marked left shift, continuing till death on the 17th day.

In Experiment II. the right shift is hardly noticeable, and the left shift commences on the 7th day and stops on the 17th day. It remains constant till the 33rd day, when there is a definite rise before death.

In Experiment III. there is no preliminary right shift and the left shift is not so marked. This becomes less on the 21st day, and gradually gets within normal limits on the 34th day. It falls below normal between the 48th and 55th days, and again on the 70th day, and then sinks progressively till death on the 80th day.

(B) *Experiments on Rabbits.*

Normals were found to be lower than in guinea-pigs, and throughout the following experiments considerable difficulty was found in counting the leucocytes in view of the normally low percentage of neutrophile leucocytes in rabbits' blood (20 to 25 per cent.) which diminished in the later stages of the disease.

June 12th	18	47	23	10	2	= 231	2120

June 12th, killed owing to bad condition.

Post-mortem.—Lungs: Scattered small nodules in both, not very numerous. Microscopically, giant-cell systems and round-celled infiltration, with one or two early caseous areas of small extent. Bronchial glands not enlarged. Liver: Apparently normal. Microscopically normal, and no tubercle bacilli seen on section. Kidneys: Many tubercles present. Section showed tubercle bacilli present and round-celled infiltration scattered through cortex and medulla. Suprarenals: Enlarged and apparently caseous. Section showed both nearly a mass of tubercles and a considerable portion of glands caseated. Spleen: Normal. On section normal and no tubercle bacilli seen. Bladder, testes, intestines, and mesentery, normal.

EXPERIMENT VI.—*Rabbit No. 3.*

June 5th: Intraperitoneal injection of ½ mg. of human tubercle bacilli emulsion.

July 17th	16	30	42	10	2	= 252	2420
July 31st	13	32	42	10	3	= 258	2410
August 7th ...	14	33	42	10	1	= 251	2420

August 7th: killed.

Post-mortem.—Showed a few scattered tubercles in the liver. Spleen normal. Scattered tubercles in omentum, one in right kidney and a few in lungs. Glands not enlarged. Chart 6 shows the change in the Arneth count graphically.

In Experiment IV. the initial right shift and subsequent fall are very similar to that of guinea-pig in Experiment I.

In Experiment V. the result is again similar to that of guinea-pig in Experiment III., and it is possible that the left shift before death in the case of the guinea-pig in Experiment III. would have been repeated here, if the rabbit had not been killed owing to its bad condition.

In Experiment VI. the Arneth curve generally follows the preceding ones on a lesser scale, but only just leaves normal limits about the 20th day.

Considering the six experiments as a whole, (1) The more severe the injection, the greater tendency is there to a right shift after injection. (2) This is followed in all cases by a left shift, its degree depending again on the severity of the injection. (3) Those animals who survive at this stage have a right shift which continues until the normal is reached. It then fluctuates but tends to fall before death.

Remarks on Results.

The danger of drawing any definite conclusions from these few cases is fully realised, but prominence has been given them owing to my attention being drawn, towards the completion of these experiments, to complement-fixation tests carried out about the same time by Besredka and Jupille,[12] and Besredka and Manonkhine,[13] on rabbits and guinea-pigs, using Besredka's antigen. In rabbits, injection with bovine tubercle bacilli always produced a negative reaction throughout the disease. Intraperitoneal injection of human tubercle bacilli produced a negative reaction on the 16th day which became positive between the 17th and 60th days, strongly positive towards the 70th and negative between the 70th and 100th days and thereafter positive on to the 135th day. In subcutaneous injections the positive phase was shorter, lasting to the 62nd day. After this it was negative or indeterminate to the 100th day, and then positive up to the 135th. The close correspondence of the two series is shown in Chart 6. The particularly interesting feature is that while Besredka obtained no result in rabbits injected with bovine tubercle bacilli, the corresponding Arneth counts in Experiments 4 and 5 (injected with bovine T.B.) showed deviations closely comparable to his results with human tubercle bacilli. The Arneth counts would consequently appear to be distinctly more sensitive than the complement-fixation results as performed by the strain of bacilli in the antigen used by Besredka. Turning now to Besredka's experiments with infected guinea-pigs, he obtained a positive result as early as the 4th day after injection, which became indefinite and variable from the 17th to 29th and 50th to 80th days, and positive between 29th and 50th and 80th and 90th days. The close connexion between these figures and the Arneth counts on Chart 5 is obvious. The value of Besredka's antigen as a diagnostic agent in human pulmonary tuberculosis has been sufficiently proved both by Besredka [14] and Inman.[15]

Comparison between Animal Experiments and Human Cases.

At first sight it appears difficult to correlate these results on guinea-pigs and rabbits with those obtained in the 30 cases of pulmonary tuberculosis previously described. It must, however, be remembered that the latter represented cases in which the infection was localised to the lungs, and the duration of the disease was far longer. In addition the Arneth counts were only samples taken over a relatively short period of the whole disease. The definite evidence of a right shift occurring in the animal experiments at the earliest stages of the most acute injections, and its tendency to occur later in the disease, help to explain the right shift obtained in Case 27. Here, in view of the age of the patient and the long duration of the disease, the right shift would presumably coincide with the secondary right shift, which tends to occur in the later stages of the animal experiments.

Some explanation can also be found for the various cases which did not appear to conform to the general average.

In Case 29 the high count might be explained by supposing the existence of a previous right shift, and would then be comparable to the left shift occurring before death in the case of the guinea-pig in Experiment III. The marked drop and subsequent rise in Case 4 find a close parallel in the Arneths of the animal experiments between the 10th and 40th days. Cases 12, 13, and 24 can be similarly explained. In the absence of further evidence, however, it is impossible to arrive at any definite conclusions.

An endeavour was made in July, 1914, to obtain Arneth counts from a case of tuberculous meningitis throughout its course in order to see if this would reveal any similarity to the animal experiments, but without success, and the outbreak of the war put an end to all further work. A case of acute (non-tuberculous) meningitis was examined daily for the last four days of life, and the results are closely comparable with the final fall occurring in Experiment III.

—	I.	II.	III.	IV.	V.	—
August 4th	36	42	19	3	0	=189
,, 5th	40	40	17	3	0	=183
,, 6th	42	42	14	2	0	=176
,, 7th	49	37	10	3	1	=170

It is noteworthy that there is an absence of the marked left shift, described by other observers as occurring in acute infections.

Concluding Observations.

In view of the many omissions and incompleteness of this investigation, the idea of publication was at first abandoned when it was found impossible personally to continue the work at the conclusion of the war, but, in view of the interesting results obtained, it was finally decided to publish the results as they stood, in the hope that their publication may stimulate further investigation of the Arneth count along similar lines. This is certainly required before it can be determined whether the Arneth count is to be definitely established as a laboratory method for the diagnosis and possible prognosis in cases of pulmonary tuberculosis.

The views of Arneth and most later observers on the reason of the shift of the Arneth count in infectious disease have been summarised by Chamberlain as follows: "An increase of leucocytes of Classes I. and II. goes hand-in-hand with low resistance or with a high degree of toxic and bacterial absorption, which is bringing about the destruction of the more actively phagocytic leucocytes belonging to Classes III. and IV."

Macfie, and Breinl and Priestley, prefer to regard the Arneth picture as an expression of the functional activity of the leucopoietic system, especially the bone-marrow, rather than one of phagocytic activity. The tentative suggestion is made that the variations in the Arneth count in infection are an index to the ratio between the degree of body resistance as shown by increased production of leucocytes, and the severity and extent of the effects produced by the infecting organism, as evidenced by their destruction.

Normally production and death of leucocytes is constant and a uniform process of the body's mechanism and the Arneth count remains constant. If, however, an infective agent can destroy more leucocytes than the body is producing, a left shift would be the result. Conversely, a greater production of leucocytes than can be destroyed at the infecting focus or foci would produce a right shift and the Arneth count would tend to return to normal, and if this still continued, a right shift would result.

A parallel series of examinations of the Arneth count and the antitryptic power of the blood should prove interesting in this connexion.

In conclusion, the invaluable suggestions and help of Dr. A. C. Inman throughout the whole course of the investigation are gratefully acknowledged. Without his encouragement and advice this paper would never have been published. My thanks are also due to the visiting staff at Brompton Hospital, to the lady almoner, whose assistance in following up old cases was of the greatest value, and to the superintendent of Frimley Sanatorium (the late Dr. Meek) where several of the cases were examined in their later stages.

THE PROBLEM OF

THE "POSITIVE THROAT" IN DIPHTHERIA CONVALESCENTS.

A CLINICAL STUDY OF 50 CONSECUTIVE VACCINE-TREATED CASES.

BY JAMES LAW BROWNLIE, M.D. GLASG.,
D.P.H. CAMB.,
ASSISTANT BACTERIOLOGIST, CORPORATION OF GLASGOW.

PROBABLY there is no more difficult and unsatisfactory problem to be dealt with in fever practice than that of the diphtheria carrier. Ker,[1] Osler,[2] McVail,[3] Osler and Macrae,[4] Bosanquet and Eyre,[5] and others bear out the truth of this contention. The very multiplicity of so-called cures is an admission of their comparative worthlessness. At various times the following amongst many others have been pressed into service as curative agents: carbolised glycerine of varying concentrations, formaldehyde, chloramine-T, flavine, urea, papayotin, lozenges, insufflations of powdered serum, toxin-antitoxin, vaccine-antitoxin, endotoxin; media containing bacilli killed in one case by exposure to chloroform, in another pulverised at the temperature of liquid air, and in a third extracted by ethylene-diamine and submitted to further tedious processes. It must be conceded that it would be difficult to furnish a better example of scientific ingenuity than the foregoing.

So much disappointment followed extended trials of many such vaunted remedies that the writer early in 1916 began the quest for some more specific and dependable application. Problems of symbiosis and saprophytism had been fascinating studies, and it appeared reasonable to assume that investigation along such lines might lead to definite findings. Much time was spent and many attempts made to discover if there might not be some constant bacterial association in the throats of carriers. Had the hope materialised the intention was to employ either a specifically made vaccine or one of the marketed antistaphylococcal or antistreptococcal vaccines against the supposed abetting organism. By the removal of this latter it was confidently anticipated that the persistent *B. diphtheriæ* would simultaneously disappear. The premise that a pyogenic organism would be inculpated appeared justifiable from the clinical observation that those cases were invariably most toxic whose local membranous lesion had marked and demonstrable pyogenic associates. Realising the apparent impossibility of success in the quest for associates, the idea of using a vaccine of the offending organism itself appealed to the writer, and was forthwith put in practice, quite independently of the knowledge of its previous tentative employment. Forty-three consecutive cases had been successfully treated when interest was sufficiently aroused in the matter to consult the literature on the subject. Nowhere did claim appear to be made either for such uniformity of results or for such a large consecutive number as the series about to be reviewed.

Effects Produced by Vaccine on Diphtheria Bacilli.

The vaccine used was made in the usual way, and was not autogenous. After a considerable number of patients had been dealt with it was realised that the diphtheria bacilli in each case did not behave uniformly in the presence of vaccine. The morphological changes observed in each instance conformed to one or other of three types:—

(1) In a number of cases a culture, characteristically positive 24 hours before vaccination, became completely negative 24 hours after vaccination. This, of course, was an ideal transformation, and apparently depended upon immediate lethal influence of the vaccine constituents on the particular bacillary invasion concerned. Of the 50 cases treated, 13 conformed to this first type.

(2) In many of the cases the transition from positive to negative was accomplished in stages. Bipolarity became barely manifest, inasmuch as the rods contained, for the most part, varying numbers of darkly staining beads or granules. One was induced to describe such a field as consisting of "beaded degenerates" or "granular bacilli," whilst the term "bacillary debris" might aptly be applied to the appearances presented after further dissolution had occurred. Negativity was thereafter obtained. Twenty-four of the cases progressed from positive to negative by stages, as above described.

(3) In the remainder metamorphosis took place in a different manner. The transition was effected through various phases or modifications of diphtheroid change. After 24 hours' association with vaccine the organisms were rod-shaped or diplo-bacillary in form, and varied much in size and shape. Subsequent swabs showed no trace of *B. diphtheriæ*.

The vaccine was clearly capable of instituting well-defined involution formation, with subsequent dissolution in the bodies of diphtheria bacilli with which it was brought into contact. Many of the involution forms were comparable with those known to be producible by alteration in optimum growing conditions.

Vaccine Administration in 50 Consecutive Cases.

The series occurred in the ordinary course of practice in an isolation hospital. There was no selection. No accessory treatments were at any time employed. It was concluded that the persistence of the *B. diphtheriæ* was due to one or other or any combination of the following four circumstances: (1) Innate lack of resistance of the hosts—mainly contributed to by the presence of a concurrent resistance-lowering condition, such as pneumonia. (2) Spread by continuity of tissue—causing infection of any of the accessory nasal or pharyngeal passages. (3) Severity of the original local involvement. (4) Individual tolerance or natural predisposition—carriers or those with bad fever histories.

Taking the somewhat arbitrary designations of mild, moderate, and severe, it was found that 16 fell into the first classification, 2 into the second, and 32 into the third. Put briefly, of the mild cases 8 had complicating diseases, 5 were carriers, and in 3 only was there no evident predetermining factor, although even they may have had an undiscoverable invasion of the antrum of Highmore or Eustachian tube. In other words, fully 81 per cent. satisfied one or other of the original premises. Of the 2 moderate cases, it may be summarised that persistence in one was conduced to by individual tolerance and the other by natural predisposition. Of the 32 severe cases, 12 had some degree of broncho-pneumonic disease, 3 had accessory passage infection, whilst 4 had a double infection of lungs and mid-ear in addition to their original severe invasions. By reason, therefore, of the coexistence of the favouring factor or factors the ground had been well prepared for diphtheritic bacillary persistence.

Since various factors may be contributory to the production and maintenance of a morbid state, careful note was taken and record kept of many circumstances which were thought likely to have ætiological bearing upon carrying. Attention was accordingly directed to questions of sex and age, the pre-existence of albuminuria, the brand of serum given, the infectious fever history of the patient, and the day of disease on which serum was administered.

The series of carriers was made up of 22 males and 28 females. Taken in conjunction with the age-incidence, such a proportion was not at variance with that obtaining in diphtheria itself. No proof, then, was forthcoming that sex, per se, exerted any particular predetermining influence.

With regard to age, it was not found that persistence of the *B. diphtheriæ* in convalescence was liable to affect disproportionately those at one time of life more than at another.

TABLE A.—*Showing Age-incidence.*

Age.	No.	Age.	No.
1-5	30	20-25	3
6-11	13	36-	1
12-16	3		

Table A shows that 60 per cent. of the patients were under 6, and that 86 were under 12. It was therefore concluded that the question of age did not arise. Except in so far as albuminuria was admittedly indicative of a severe initial lesion, pre-existing toxic nephritis had little, if any, influence in determining late faucial bacillary persistence. 25 had been treated with B. & W.'s serum, 25 with P.D.'s. For all practical purposes, therefore, serum variation did not govern in any measure the future conduct of the *B. diphtheriæ* in each instance.

The most noteworthy point for consideration was that of previous infectious disease, more especially as it related to involvement of the respiratory tract and lungs. In many of the cases the diphtheritic attack had followed closely a previous measles or pertussis. In fact, the former infection was frequently a convalescent sequel of the latter. The very lack of resistance which predisposed to the diphtheritic infection presumably militated against the early dispersal of the invading bacilli. It appeared that mucous membrane damaged by the inflammations accompanying such fevers as measles and pertussis, especially when further violated by diphtheritic toxin absorption, formed a very suitable locale for the perpetuation of the *B. diphtheriæ*. 74 per cent. had been, in the more or less immediate past, the subjects of just such damaging influences as produced indifference to the presence of an organism which readily assumed saprophytic propensities.

It was anticipated that the longer the initial delay in administering serum the greater would be the liability to subsequent positivity. Patients saturated with toxin absorbed for three or more days would not be expected to have many antibodies (antitoxic or antibacterial) in their blood streams. Although the antitoxic properties of the latter were artificially enriched by the addition of antitoxin, no attempt was made to provide antibacterial substances.

TABLE B.—*Showing the Day on which Serum was First Injected.*

Day of illness.	Patients.	Day of illness.	Patients.
First	2	Sixth	6
Second	14	Eighth	1
Third	4	Twelfth	1
Fourth	5	Fourteenth	2
Fifth	14	Twenty-first	1

Thirty-four did not receive serum until the supposed third day or later (Table B). In fact, 25 did not reach hospital until the fifth or later day of illness. It was concluded, therefore, that length of untreated illness bore a direct relationship to probability of becoming a carrier.

Until a considerable number of cases had been dealt with, the possibility of simple coincidence bulked largely in any interpretation put upon the cures. Consequently, it was necessary to find some evidence which would negative such a conclusion. In the first instance, the vaccine was reserved for such patients as had been in residence for unduly prolonged periods. This was done deliberately, as most positive throats clear up sooner or later without interference. The successful application of the vaccine during the earlier periods of convalescence might have been inconclusive, since it was open to argument that the organisms were disappearing in any case, and that it was fallacious to credit the vaccine with their removal. In order to demonstrate that such a view was untenable, opportunity was taken to commence treatment at very varying periods of residence. Table C makes this clear.

TABLE C.

Fifth	3	Twelfth	1
Sixth	5	Thirteenth	3
Seventh	2	Fifteenth	2
Eighth	10	Sixteenth	3
Ninth	5	Twentieth	1

It could not readily be assumed that in 50 consecutive cases, treated over periods ranging from the third to the twentieth weeks, mere coincidence offered sufficient explanation.

Table D indicates the dosage given in the series of cases.

TABLE D.

No. of organisms.	Cases.	No. of organisms.	Cases.
10,000,000	11	50,000,000	2
20,000,000	17	60,000,000	1
30,000,000	13	200,000,000	2
40,000,000	4		

In the majority a limited number of injections was effective.

TABLE E.

Doses of vaccine.	No.	Doses of vaccine.	No.
One	24	Five	3
Two	15	Seven	1
Three	5	Eight	1
Four	1		

Table E shows that by vaccinating every fourth day 44 of the cases, having received at most three doses, could have been dismissed with two consecutive "negatives" on the eleventh day. The time consumed in attaining our object varied within considerable limits—namely, 1 to 44 days.

TABLE F.

Days.	Cases.	Days.	Cases.	Days.	Cases.
One	19	Seven	3	Fifteen ...	1
Two	3	Eight	2	Twenty-four	1
Three	1	Nine	2	Twenty-five	1
Four	1	Eleven	1	Thirty	2
Five	7	Thirteen ...	1	Forty-four ..	1
Six	3	Fourteen ...	1		

Table F reveals these facts. Thirty-seven cleared up within a week, 7 within a fortnight, whilst only 6 took longer. It may fairly be accepted that, so far as the time factor was concerned, vaccine treatment of "positive" throats was unassailable by comparison with any of the other means advocated. On account of the exigencies of the situation, nearly three-fourths of the patients were dismissed within a week of the completion of treatment, as it was impracticable to retain large numbers for observation purposes. Fully one-fourth, however, remained for from 8 to 27 days without manifesting renewed "positivity" or sustaining reinfection, and this in spite of the fact that there was no segregation nor attempt at protection, as all remained in a receiving ward, liable at any time to the incursion of acute and virulent cases. If there had been any liability to reinfection every facility was offered. Such a test, of course, was unusually and unnecessarily severe, as no person outside of a hospital ward was ever likely to be the contact of such concentrated infection as were these patients. That they resisted faucial reinvasion may with confidence be credited to the provision of artificial specific antibodies.

No untoward effects were noted on the vaccinated patients. Pulse-rates were moderately increased for a few hours, the respiratory rate was mostly unaffected, pyrexia and local pain or stiffness were quite exceptional.

Administrative and economic points of view were fully satisfied, for, with the advent of war, retrenchment became a password, and any measure likely to check the rapidly mounting maintenance costs was welcomed. Vaccine treatment of the positive throat in diphtheria, when judged by a money-saving standard, was of considerable value. By a comparative estimate of averages, it was computed that the term of residence of a carrier was longer by four weeks than that of the non-carrier. The former cost the chargeable authority in food alone 35*s.* more than the latter, and if the term of residence of the annual total diphtheria admissions had been reduced to the reasonable average of five weeks fully £1600 might have been saved. However, such figures of cost need not be multiplied, as sufficient light has been thrown upon this aspect of the subject to justify the economic soundness of vaccine therapy in the positive throat of the diphtheria convalescent.

Conclusions.

1. Local antiseptic throat applications are unreliable cures for the carrier and the positive throat.
2. Diphtheria vaccine produces well-defined degeneracy in morphological appearance of the cultured organism, followed by its complete dispersal from the locality invaded.
3. In the past the diphtheria carrier has been subjected to hospital residence for weeks, perhaps months, which were avoidable.
4. Diphtheria vaccine is effective in the treatment of the positive throat of diphtheria convalescents, and its use is administratively and economically sound.

UNIVERSITY OF OXFORD.—Dr. Charles P. Symonds has been elected to a Radcliffe Travelling Fellowship for three years.

IT was announced at the annual meeting of the Academy of Medicine of Paris that the Prix Berraute for researches on cancer was awarded to Dr. Alexander Paine, director of the Cancer Hospital Research Institute, and Dr. Albert Peyton, director of the Military Laboratory for Cancer, at l'Hôtel Dieu, Paris, for their joint investigations on the subject.

LIFE ASSURANCE AND GLYCOSURIA.

BY R. T. WILLIAMSON, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER.

QUESTIONS often arise with respect to life assurance and glycosuria which are of importance both to the assurance company and to the proposer. Several of these will be considered in this note.

Family History of Diabetes.

In the medical report required by a few companies a question is specially asked, if any member of the proposer's family has suffered from several diseases regarded as hereditary; amongst these diabetes is included. But in the majority of the medical report forms with which I am acquainted, no question is specially asked respecting diabetes in the family. This information, as regards near relatives, will, however, be furnished by the usual family history required by almost all companies. The question arises to what extent a family history of diabetes (whatever this may actually mean) should lead to an increased charge for life assurance. The statistics of insurance companies might throw some light on this point; but more satisfactory evidence is furnished by statistics indicating the percentage of cases of diabetes in which a family history of the disease is obtained.

I have not taken careful notes of the family history in most of the cases of diabetes I have seen, but I have notes on three series of consecutive cases which are sufficient to be of service in this respect. In 1898 I published the statistics in 100 consecutive hospital cases. More recently I took careful notes on this point in a series of 300 consecutive private cases, and quite recently in another series of 100 consecutive private cases.

Cases of diabetes.	Family history of diabetes in—
1st series of 100 cases	13 = 13 per cent.
2nd ,, 300 ,, ...	76 = 25 ,,
3rd ,, 100 ,, ...	23 = 23 ,,
500 ,, ...	112 = 22·4 ,,

Therefore we may conclude that the percentage of cases of diabetes in which a family history of the disease is obtained may be fairly stated as 22. (Control statistics show that in 50 consecutive cases of other diseases (non-diabetic) no family history of diabetes was obtained.) Usually when a family history was obtained, the diabetic patient could only recall one member of the family who had also suffered from the disease. But occasionally 2, 3, 4, or more cases of diabetes had occurred in the diabetic patient's family.

The following are a few instances of members of the same family suffering from diabetes:—

1. Two sisters, father, father's sister, father's father, father's grandfather.
2. A medical man, his father, father's mother, and father's brother's son.
3. Father and mother and three sons.
4. In a family of four (two brothers and two sisters) two brothers and one sister suffered. They lived in different towns and suffered at different periods.
5. Father and two sons.
6. Three sisters.
7. Three brothers.
8. Father, two sons, and two daughters.
9. Two brothers, the father, and the father's mother.

Many instances of brother and sister, or two brothers, or two sisters suffering from diabetes were met with in the 500 cases specially questioned.

A history of diabetes in one member of the family would not, of course, be regarded as requiring an extra charge for life assurance. But I think a minimum extra charge would be desirable, if we find that (1) two brothers of the proposer or two sisters, or one brother and one sister have suffered from the disease; or (2) if both parents have been diabetics (a very rare occurrence) and also one brother or sister of the proposer; or (3) if one parent and a sister or brother of the other parent and also one brother or sister of the proposer have been diabetic; or (4) if one sister or brother and one of the parents and one of the grandparents have been diabetic. These extra charges would be especially desirable if the patient were of the Maltese, Hebrew, Hindu, or western Asiatic races.

Detection of Grape-Sugar in the Urine.

(1) If Fehling's test or one of its modifications should give a reaction for sugar in the urine, and other symptoms of diabetes are noted, the case is, of course, permanently rejected without further consideration.

(2) If we have no symptoms or indication of diabetes, but Fehling's solution (or some modification thereof) is reduced *definitely*, the case should be rejected, temporarily at least, even though the reduction is very slight. Mostly these cases are due to a small amount of sugar in the urine, but sometimes to other substances. Repeated examinations and much care are required before a fair opinion can be given respecting their exact nature. These observations take up much time, and I think if they are undertaken, or required, a separate fee should be paid for them. At a later date the results may be submitted and the case reconsidered, if the proposer or the company so desire.

(3) When the reduction of the Fehling's solution is *indefinite*, before rejecting the case confirmatory tests for sugar should be tried at once, within the next 24 hours, and the report withheld for that time or longer. If the indefinite reaction is due to a trace of sugar the case should be rejected temporarily; if indefinite, but not due to sugar, I think the case may usually be accepted.

The confirmatory tests for glucose in groups 2 and 3 which I have found most useful are the phenyl-hydrazin test, carried out in a test-tube (without the use of any water-bath), and the fermentation test, carried out in an inverted test-tube closed with a stopper perforated by a glass tube bent twice at right angles (a control test-tube with normal urine being placed by the side of the one containing the suspected urine). I have previously described both of these tests in detail.[1]

If we obtain by these tests no indication of glucose, the outlook is more satisfactory. The nature of the substance which had reduced the Fehling's solution, if the reaction is definite, should be determined if possible by chemical tests.[2] The exact rating will differ according to the nature of the reducing substance. If we find the reducing substance is grape-sugar, I think most physicians will agree that the case should be rejected, at least temporarily, however small the amount; and I think most companies would reject permanently.

But later, if the proposer and the company desire, the cases may be reconsidered in certain instances, when the results of a number of observations can be furnished. Most cases at this reconsideration would have to be rejected again, and rejected permanently, I think; but in very rare instances a case might be accepted if the results of a number of observations can be presented. These observations are of importance to the proposer as regards future treatment and mode of life, and should be carried out by those who undertake the treatment; but, as will be mentioned subsequently, it is improbable that assurance companies will care to recommend them or pay for them, except in very rare instances, on account of practical difficulties.

The first point is to determine if the slight glycosuria is permanent or temporary by testing a number of specimens.

The urine specimen tested should not be the early morning urine, but one passed in the latter part of the day, and best after a meal; in slight cases of glycosuria the morning urine is often quite free from sugar, though urine passed in the latter part of the day may contain sugar in considerable quantity.

If the glycosuria is permanent—i.e., detected every day—the urine is tested, or if the glycosuria is intermittent the case should be rejected, however small the amount of sugar. If glucose is detected once only and then disappears, and is not detected again after a number of examinations, and the urine is free from sugar at the end of one month, the condition may have been a temporary glycosuria. In such cases it is desirable to determine if the power of sugar destruction is reduced or not. A common method is to give 100 g. of glucose, dissolved in a quarter of a litre of water, or tea, which is taken on an empty stomach before breakfast. If the power of sugar destruction is diminished then sugar is found in the urine from half an hour to three hours afterwards. If the power of sugar destruction is normal the urine will be free from sugar after this dose of glucose. A convenient, though less accurate, way of testing is that the proposer should take a midday meal containing a quantity of sweet food equal to 100 g. of grape-sugar. A rough test is three-quarters of a pound, or one pound, of *sweet* grapes. The bladder is emptied just before the meal. Then urine is passed about an hour and a half after the meal and again three hours after the meal. If these urine samples fail to reduce Fehling's solution the power of sugar destruction is normal or not markedly reduced. If one or both of these urines reduce Fehling's solution the power of sugar destruction may be considered diminished.

If the urine gives a reaction for sugar on one examination (at the examination for life assurance) and not at subsequent examinations, but the power of sugar destruction is reduced as shown by the test just mentioned, then I think the case should be rejected. These cases may be described as cases of diminished power of sugar destruction in which temporary glycosuria may be produced occasionally by various causes, and I think they are best rejected, though it does not necessarily follow that diabetes will develop later.

But if sugar is detected once only, if we have no diabetic symptoms, if the amount of sugar is small, and if during the next month several examinations of urine passed in the latter part of the day show that it is free from sugar on an ordinary mixed diet, and if the power of sugar destruction as tested in the way just mentioned is not diminished, then I think the case may be accepted with an extra charge, especially if we obtain a history of excesses in diet or other unusual conditions at the time the glycosuria was detected. Only this small group of such cases can, in my opinion, be safely accepted. Of course, in such observations the proposer must be completely trusted to carry out the instructions fairly; hence probably few companies would be willing to accept the results, and most companies would regard the detection of sugar on one occasion as ground for permanent rejection. But these observations are all of much value to the proposer with respect to future dietetic treatment.

---

[1] See writer's articles in the Practitioner, December, 1898, and August, 1900, and book "Diabetes Mellitus and its Treatment," Lond. and Edin., 1898, pp. 19 to 23 and 35 to 38.

[2] See writer's book, "Diabetes and its Treatment," Lond. and Edin., 1898, pp. 33 and 34.

As examples of the rare cases of glycosuria just described I may mention the three following.

Twenty-five years ago I examined a man, aged 34, for life assurance and found that the urine reduced Fehling's solution, but no diabetic symptoms could be detected. I tried confirmatory tests, phenyl-hydrazin and fermentation, and proved that the reduction of Fehling's solution was actually due to grape-sugar. A second sample of urine examined two days later was quite free from sugar. Though 25 years have elapsed, he is in good health and no symptoms of diabetes have ever developed.

In another case sugar was detected in the urine of a young man of 25. A few days later it was free from sugar. Five years later it was still free from sugar. Last year I examined the urine again and found it still free from sugar—that is, over ten years from the time the temporary glycosuria was first detected.

In another case the urine of a man of 35 was found to contain a small amount of sugar. (By the phenyl-hydrazin test and fermentation I proved this was grape-sugar.) A few days later I found the urine free from sugar. I examined the urine last year—ten years after the glycosuria had been detected and found it still quite free from sugar.

Termination in Cases of Glycosuria.

Though I think only the one very small group of cases of glycosuria just mentioned can safely be accepted (with an extra charge) by an assurance company, we must not conclude that all other cases necessarily end badly. There is, however, no hardship in excluding them; these people can invest their money in other ways. The course of the affection is probably influenced by the mode of life, but as the assurance company cannot be sure what mode of life will be followed it is usually best to avoid the risk.

Now the question is often asked what happens in the cases of slight glycosuria detected for the first time at the examination for life assurance. I have indicated the further course of such cases in a chart previously published.[3]

(1) The glycosuria may promptly disappear and never be detected again, and complete recovery may occur (as in the three cases already mentioned in this note). This course is more probable in cases in which the power of sugar destruction is not diminished. When, however, the power of sugar destruction is diminished, as indicated by the 100 g. glucose test (or some modification thereof), we have greater risk that the course will be that indicated in one of the following groups.

(2) The temporary glycosuria may be followed for many years by an occasional or intermittent slight glycosuria which never develops into a true diabetes, even after 10 or 20 years or longer.

(3) In other cases this intermittent glycosuria after many years, 5, 10, or 20, or longer, develops into a severe diabetes, ending fatally.

(4) The temporary glycosuria may be followed by an intermittent diabetes mellitus.

(5) Or by a *mild* form of persistent diabetes.

(6) Or by a persistent *severe* form of diabetes.

Forms 4 and 5 may develop later into severe persistent diabetes. In forms 2, 4, and 5 death may occur after many years, through an intercurrent disease having no direct connexion with glycosuria.

All physicians who have been in practice over 20 or 30 years will be able to recall instances of these groups. As examples of group 2 I may mention two cases of glycosuria, in which the glycosuria has been intermittent, gradually becoming less frequent, for 20 and 10 years respectively.

The following are examples of group 3.

A patient had suffered from slight intermittent glycosuria for 24 years. Then severe diabetes suddenly developed and ended in diabetic coma.

In another case after 17 years of slight and intermittent glycosuria severe progressive diabetes suddenly developed, and after a few months death occurred from cardiac failure.

In another case after a period of glycosuria the urine became free from sugar, and the patient remained in good health and had no symptoms, and the urine was not tested for many years. At the end of 12 years diabetic symptoms developed and the urine was found to contain sugar, and in a very few days death occurred from diabetic coma.

Importance of the Detection of Glycosuria to the Proposer.

The most important point with reference to life assurance and slight glycosuria is the advantage of the urine examination to the proposer, if he is informed of the result and its significance not exaggerated. It is to his advantage, that if the urine contains a little sugar it should be detected *early*.

It is a rule of many assurance companies that no information as to the result of the medical examination should be given by the medical officer to the proposer. But in cases of glycosuria I think, in the interest of the proposer, he should be informed why he has been rejected. This could be done best by the medical examiner, who could also inform the proposer of the exact significance of the glycosuria and of the importance of treatment, and could do this without causing alarm.

We cannot claim to be able to prevent diabetes, but we do know something of the ætiology of the disease, and we may be able to do something to prevent the slight glycosuria developing into a severe diabetes.

(1) If the urine contains a small amount of sugar daily, or if the condition is one of intermittent glycosuria, the rigid dietetic treatment (with or without drugs) suitable for a mild form of diabetes should be carried out.

(2) If the urine contains sugar at one examination but on further examination is found free from sugar, though the power of sugar destruction is impaired, then all sugar and sweet foods, sweets, chocolate, and sweet drinks, especially sweet alcoholic drinks, should be excluded from the diet, and the carbohydrates should not be excessive, but an average quantity can be taken. (Starch is probably much less injurious than sugar.)

In both of these classes the mode of life should be altered if necessary. Great mental strain and excessive brain work should be avoided if possible. A fair amount of physical exercise should be taken, and the total quantity of food should not be above the average; also I think that small frequent meals are best. It appears probable that excess of sugar in the diet, sweet beverages, especially those containing alcohol and much sugar, excessive brain activity or anxiety, deficient physical exercise, and obesity or excess of food, often increase the risk of the diabetes or accelerate its onset, especially in individuals who have a family history of diabetes.

(3) When the urine contains sugar on one occasion only, and we find no defective power of sugar destruction, then the only precaution necessary is to limit the amount of sugar and sweet food, or best to abstain entirely from sugar, sweets and chocolates, and very sweet food or drinks.

Dread of Diabetes.

When the proposer is informed of the glycosuria it is important that he should not be alarmed. Treatment should be urged, but the favourable features in the prognosis should be emphasised, when this is justified by the condition found. He should clearly understand that though he is unsuitable for life assurance it does not follow that serious and progressive diabetes will necessarily occur, and that he may be able to do much to prevent such an event. We occasionally meet individuals who suffer greatly from the "fear of diabetes," when informed that a little sugar has been found in the urine—a neurosis similar to that known as "syphilophobia," which is most difficult to check I have seen a number of such cases. In one instance the neurosis continued for over two years. A trace of sugar had been detected once only, at the examination for life assurance. The man was the son of a medical man and was acquainted with many medical terms. A terrible dread of diabetes developed and continued, though the urine was examined repeatedly by numerous medical men and no further glycosuria ever detected. Finally, he visited Carlsbad, where again no sugar could be detected in the urine, and treatment was refused. He returned home still distressed and unsatisfied. He consulted me after two years of mental anxiety. I examined his urine, and found no trace of sugar, even after a meal containing a great excess of sugar.

---

[3] See Practitioner, June, 1911.

Such instances show how important it is that the proposer should not be alarmed when he is informed of the slight glycosuria.

A NOTE ON THE DIAGNOSIS OF

TUBERCULOSIS IN RECRUITS AND PENSIONERS.

BY JOHN GUY, M.D., D.P.H. CAMB., F.R.C.P. EDIN.,
TUBERCULOSIS OFFICER, CITY OF EDINBURGH; LECTURER ON TUBERCULOSIS IN SCHOOL OF MEDICINE OF ROYAL COLLEGES, EDINBURGH.

THE relation of the tuberculous patient to war service is interesting. In the earlier days of the war we heard a great deal of the cured consumptive who had joined the army. Institutions in their reports apparently vied with each other as to the number of their ex-patients who were at the front. At one time it appeared that the motto which would possibly be inscribed over all sanatoriums was "We won the war." After a little experience of the cured consumptive, and a short period of observation, the War Office issued stringent instructions to the intent that no consumptives need apply. As far as one could judge the orders meant total rejection for any recruit who had been at any time in a sanatorium or under treatment at a tuberculosis dispensary. This knowledge speedily reached the laity, and those men who were not over-anxious to run the risk of being killed were delighted if at any period in their lifetime they had been under treatment for actual or suspected tuberculosis. I answered not a few letters from recruiting boards who were desirous of testing the truth of some of the assertions by recruits of attendance at the City Dispensary. Several of the cases inquired into were genuine tuberculous patients, but others whom we had classed as slight bronchitis or some other non-tuberculous condition attempted, and sometimes attempted successfully, to evade service on the strength of having attended the dispensary once or twice many years previously.

The Attitude of Recruiting Boards to Tuberculosis.

Nothing apparently scared the recruiting boards like the word tuberculosis. I could place my finger on one or two men who, to my own personal knowledge, secured admission to a sanatorium for the purpose of avoiding service, and who, as far as I know, had no tuberculous disease in the lungs at all. One at least confessed to me that he had "got the wind up," and on being told that there was nothing wrong with his lungs, inquired anxiously as to whether if he could contract a cold it would make any difference. He gained admittance to a sanatorium all right. I suppose he will be returned as one of the cures discharged in the year 19—, and now, at the beginning of 1920, is well and working.

It was a good thing in those days to be supposed to have consumption, but it is a much better thing now. The day of pensions has arrived. The number of men who are now in receipt of pensions for tuberculosis and who, in my judgment at least, are not suffering therefrom is truly alarming. I have seen in one week alone at least eight men who, in my opinion, showed either no evidence of pulmonary tuberculosis, or at most presented what might be interpreted as an old cicatricial condition, the age of which no man could tell, but showing no signs of activity and producing no disability whatever. Nevertheless they had a pension. My experience is, I take it, not unique. I have had much confirmation of this state of affairs from my brother tuberculosis officers by written and conversational inquiry.

The cause of this state of matters is complex. While the war was in progress it was perfectly natural, and I believe not uncommon, for some men to attempt to get out of the trenches for a longer or shorter period on the pretext of illness. The conditions of life, the physical stress, and the mental strain produced in many the constitutional syndrome which is often presented in tuberculosis. This made it difficult to give an exact diagnosis of any real or supposed illness, and if any departure from the normal were discovered in the lungs too often the man was labelled as tuberculous and discharged as unfit for further service.

Too frequently in the well-known 1835 certificates the diagnosis rested on an X ray finding of that very unsatisfactory thing, peribronchial thickening, or some such indefinite condition. Yet these 1835 certificates were a power in the land. Whoever signed them had to state whether it was essential or not that the man should go to a sanatorium. If he signed in the affirmative, then to a sanatorium the man was sent, and whenever he appeared at a future medical board for reassessment the fact that he had been in a sanatorium was considered as proof that he had had tuberculosis.

Generous Pensions.

Again, now that the war is finished, it is becoming known that the scale of pension is much more generous in the case of the tuberculous than in the non-tuberculous, and, in addition, there is the chance of the extra domiciliary grant equivalent to 10s. per week. This makes it profitable to be labelled "tuberculous." Consequently, many men are now, after demobilisation, discovering, or imagining, that they have a cough and a spit in the morning; that they have lost weight and are breathless on exertion; and too often on such flimsy evidence are classified P. 25, which, being interpreted, means pulmonary tuberculosis. After a medical board has given such a finding these men ultimately wend their way to the tuberculosis officer for the district. Many of them I turn down promptly and inform them that in my judgment they do not suffer from tuberculosis. To some of them I appear as an angel of light, but to others a rock of offence. At times, instead of giving a definite judgment at once, I admit them to the sanatorium for a period of observation. If they are found then not to be suffering from tuberculosis that does not necessarily finish the case, as the next time they appear before a board for reassessment they have then, as added proof of the presence of disease, the fact that they have been in a sanatorium.

Another source of error is that at times indefinite cases present themselves before a board on which there is no member who has had special experience in the difficult branch of chest work. Such a board is usually timorous and doubtful of its own experience. It plunges for tuberculosis every time. It does not fully realise the weight its decisions carry. At other times the board may have had the assistance of a tuberculosis "expert." Such an individual usually sways the judgment of the board, as he does the examination, and the other members do the clerical part of the work. The assistance of the expert does not always improve matters. Tuberculosis experts are divisible into two classes, wise and unwise. The latter, suffering from grandiose ideas, are prepared to diagnose pulmonary tuberculosis at a moment's notice anywhere and everywhere, and if one such becomes the guiding spirit in a medical board still further confusion may result.

A Special Chest Board.

In order to improve the present condition of affairs, all chest cases, tuberculous and non-tuberculous, should be dealt with by a board composed of members all of whom should be experienced in chest work. Not less than two should examine every case, and when any doubt exists the opinion of all the members would, of course, be obtained. All chest disabilities discovered or suspected by the other boards should be referred to the special chest board for final decision. All new claims of chest disabilities by demobilised men should be dealt with by the chest board.

Whenever a man has had sanatorium or dispensary treatment this board should be authorised to ask for a special report on the man's case from the tuberculosis officer for the district in which the man comes from. There should be no difficulty in this, as I think we all file the discharge report of our sanatorium cases. If such report were received by the special board it could be placed with the man's papers and kept as a permanent record.

The special board should not be asked to work in the same room in which two or three other boards are working and where the men are undressing. It is quite impossible often to do good work owing to the noise, and more particularly is this so if any of the other boards happen to be an aural one. The chest board might reasonably occupy rooms at one of the tuberculosis dispensaries, where an X ray installation is at hand and where there are facilities for the examination of sputum.

Such special boards should be asked to pay particular attention not only to the presence of any lesion, but to its activity and to the amount of disability arising. As indicative of activity the board should demand in preference to symptoms signs, such as rapid or marked loss of weight, a medical certificate of hæmoptysis or fever, the presence of tubercle bacilli in the sputum, and the presence of persistent localised crepitations.

Too much stress should not be laid on slight impairment of the percussion note in the right apex or the presence of broncho-vesicular breathing or apical retraction. These may quite truthfully represent a lesion, but the important points are activity and disability. Such a board might also very properly form a final court of appeal in all doubtful cases seen by the medical referees.

Throughout this paper I am not discussing the genuine consumptive, but rather the indefinite case simulating pulmonary tuberculosis. The man should have the benefit of any doubt after exhaustive examination and be given a high assessment. The period between examinations for reassessment should, as a rule, be not more than six months. As the cases come up for review and pass into the quiescent or arrested condition they should be reduced by 10 or 20 per cent. at each examination, so that the reduction in pension would correspond with the permanent improvement in health.

Could such a board as I visualise be instituted for each large centre, I am confident it would at once justify its existence and be a source of strength to all engaged in this most difficult and trying work.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A BONE CONDITION ANALOGOUS TO RICKETS IN A CHILD OF FIVE MONTHS.

BY HILDA K. BRADE-BIRKS, M.SC., M.B., CH.B.MANCH., M.R.C.S., L.R.C.P.,
MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE, SALFORD.

IN view of recent discussions on the ætiology of rickets the following symptoms occurring in a breast-fed infant appear to be worth recording.

A girl, born July 16th, 1919, the sixth child of a mother aged 31 years, was brought to one of the Salford corporation guilds. At the age of 4 weeks, when first weighed, the baby was a healthy, normal, breast-fed child weighing 8 lb. 1 oz. For three weeks she continued to gain normally, weighing 9 lb. 5½ oz. at the age of 7 weeks. From that time progress was less satisfactory and the weight fell below the normal. At the seventeenth week, when the child weighed 10 lb. 7 oz., symptoms analogous to those of rickets were observed. Three weeks later the infant was brought to the clinic for special medical examination. At this time the mother had noticed a considerable decrease in activity (the child showed no inclination to kick, and lay listless all day). The forearms were bent with an outward curve. There were comparatively large swellings at the distal ends of the radius and ulna in either case. The radial swellings were the greater, and those of the left forearm were more marked than those of the right. In the lower limbs the tibiæ exhibited marked forward and outward curves, each tibia having an obvious swelling of the anterior part of its distal extremity. Another swelling occurred on the right tibia at the lateral and anterior part of its proximal end. The head was normal in shape and size, and the spine presented no unhealthy symptoms. The skin of the whole body was dry and slightly rough. Constitutional symptoms (slight sweating of the head at night, listlessness during the day, enlarged abdomen, slight alimentary disturbances, &c.) were commencing but were not marked. The child was still breast-fed only and weighed 10 lb. 13 oz.

History of the mother.—As the child had been breast-fed it was thought advisable to inquire into the history and condition of the mother. The latter had had six living children, as follows: the first at the age of 22, the second at 24, twins at 26, a fifth child at 28, and the girl referred to above at 31. Of these, she lost two, one of the twins and the fifth. The mother herself is thin but muscular; she is one of nine healthy children all living. The last confinement was normal. The financial circumstances of the parents were fair, the husband being in the army, and the mother had apparently been well nourished during pregnancy. Her diet included no butter, but she had a pint of milk every day during the whole of her pregnancy and after. Her breakfast consisted of bread and margarine, bacon (sometimes), and any other thing that could be got at the time. Dinner consisted of fish or meat stews, potatoes, and vegetables of all types. Tea—bread and margarine. The pint of milk daily was used between meals in the form of gruel. During the first four months of pregnancy the mother was a waitress at a nurses' canteen and got very good food. The money she saved helped her through the other months and her confinement. The lungs and heart were normal and the urine free from albumin and sugar. The mouth had been well cared for and was free from any trace of pyorrhœa.

Samples of breast-milk were taken on Dec. 12th, 1919. Mr. G. D. Elsdon, Salford borough analyst, was kind enough to examine these, and to supply me with the following figures :—

	Right breast.		Left breast.	
Fat	1·9 per cent.	....	0·3 per cent.
Proteins	1·2 ,,	....	0·9 ,,
Ash	0·2 ,,	....	0·2 ,,
Sugar	7·3 ,,	....	7·3 ,,
Total solids ...	10·6 ,,		8·7 ,,

In comparison with the averages of Pfeiffer and of Luff this milk is particularly deficient in fat (the sugar percentage is slightly above normal, the protein subnormal).

Massage treatment.—When the infant was first noticed to have rickets-like symptoms (Nov. 11th, 1919) massage treatment was begun. Until Dec. 2nd, 1919, breast-milk was the sole food, but as progress was still unsatisfactory, alternate feeds of boiled cow's milk with water and of breast-milk were then ordered. Within a week an obvious improvement took place, the child having gained 6½ oz. Since the analysis of the mother's milk the child has been weaned gradually, and boiled cow's milk substituted. The massage has been continued to date three times a week. Apart from a general improvement in health, all the affected bones of the limbs have become considerably straighter, and the wrist and ankle swellings have been correspondingly reduced. On Jan. 6th, 1920, the child weighed 11 lb. 14 oz.

Present condition (March 9th, 1920).—The child now weighs 13 lb. 8½ oz., and is in very fair condition. The bones are practically normal in shape, but rather soft, and the flesh is not yet very firm. However, the child is bright, active, and contented. The teeth are appearing, though none are yet quite through. Massage is being given twice weekly. The child has had a small quantity of virol for the last few weeks, otherwise the diet is boiled cow's milk. No cod-liver oil has been given.

The term "analogous to rickets" is used to prevent controversy as to terms. There seems to be a current belief that typical rickets cannot occur in a child so young; however, the signs in this case were as typical as any I have seen.

TWO CASES OF ICHTHYOSIS HYSTRIX IN THE SAME FAMILY.

By L. MEREDITH DAVIES, M.D. OXON., D.P.H.,

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER OF CARDIGANSHIRE.

THE following two cases are of interest for several reasons. Firstly, the comparative rarity of the disease; secondly, its congenital origin; and thirdly, the unusual positions of the warty growth. The two cases were found during the medical inspection of the schools in the county, the patients being brothers.

Family history.—The father's brother married the mother's sister. History of tuberculosis on father's side. No history of skin trouble or of illness of importance on either side. The mother's sister has four children, two of whom—the eldest daughter, aged 10 years, and the baby, aged 10 months—have typical ichthyosis.

Origin of disease.—The mother describes the condition of the two boys at birth as follows: "They were born with their hands and their feet covered with a film, as if whitewashed." The white film refused to be washed off, but later, when the superficial layers had loosened, the underlying skin was rough and dry. When about one year old warts were first noticed on hands and feet, and these gradually spread and increased over rest of body. The other two children, who are unaffected, have been sleeping with them, and using the same towel. The mother has paid great attention to washing the boys.

Present condition.—The two brothers are aged 12 years and 9 years respectively. The skin of the face is dry and scaled, but clear of warts. Above the collar is a definite ring of greyish warts. The rest of the skin of the body is dry and scaly, and superimposed are numerous warts, varying in number in different localities. In the neighbourhood of the joints, dorsal surface, and palms of hands and axillæ the warts are especially numerous, and so closely packed that no normal skin can be seen. The penis also of the younger boy is covered with warts. The warts are greyish in colour, and measure about 2–3 mm.

The great number of the warts can be emphasised by the fact that the previous diagnosis made was "warty growth of skin." The boys have been sent to hospital, but no good result has been obtained. The present treatment consists of washing with cuticura soap and the application of olive oil.

TOTAL INVERSION OF THE PARTURIENT UTERUS.

By W. G. EVANS, L.R.C.P. EDIN.

THE interesting case of total inversion of the parturient uterus reported by Drs. H. Townsend-Whitling and Norman Glover in THE LANCET of Feb. 28th induces me to report a similar case that occurred in my work last summer.

My case was also a primipara aged 28 years, which followed a normal and easy course until the birth of the child, when an alarming gush of hæmorrhage occurred which caused me to direct my attention to the condition of the fundus; failing to find it, I concluded that I had to deal with concealed hæmorrhage, and on looking to see if any loss was going on I found the whole uterus extruded with the tubes standing out at either side as tense hard cords. The placenta was lying on the sheet and there was no hæmorrhage. Realising that time was of the greatest importance, my right hand being gloved, I placed a finger and thumb on the outside of the stretched tubes as far up as I could, being careful not to grasp the neck of the tumour; I pressed upwards as firmly as I could and the whole thing slipped back at once. Passing my hand into the uterus to feel if the inversion was fully reduced I found a tumour, the size of a small apple, with the central cavity the depth of the first phalanx of my index finger. Supporting the fundus with my left hand on the abdomen and pressing my knuckles against this, it spread out at once. There was no shock or hæmorrhage and convalescence was normal.

The absence of all serious symptoms was due, I believe, to the promptitude with which the condition was relieved, the reduction not taking more than from 20 to 30 seconds, and the involution not lasting more than about two minutes.

Beckington.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on March 19th, Mr. **HERBERT TILLEY**, the President, occupying the chair.

Attic Suppuration with Latent Antral Disease.

The **PRESIDENT** showed an instructive case in which chronic suppuration of the left attic gave practically no indication of the extensive suppuration in the antrum and mastoid cells which was found at the operation. The patient, a girl aged 18, complained of nothing more than some deafness and occasional pain in the left ear. Shrapnell's membrane was seen to have a small perforation, and suction by means of a Peters-Siegel's speculum was applied, when pus exuded. Deep pressure over the outer walls of antrum and mastoid process caused slight pain. The patient having been advised against operation, it was difficult to obtain consent, but the speaker did the conservative mastoid operation and found the antrum full of pus, and a tract of suppuration extending through the mastoid cells and denuding an area of the lateral sinus. The President contended that the case showed the need for discarding the operation of ossiculectomy, still advised by some otologists, for the treatment of chronic attic suppuration, particularly because, in most of these cases, the real focus of the disease was in the antrum or the mastoid cells. It was difficult to persuade people whose drum seemed healthy that there was serious disease deeper.

Mr. **ARTHUR CHEATLE** congratulated the President on the case, also the patient, and expressed his strong agreement with the exhibitor's remarks on ossiculectomy.

Mr. W. **STUART-LOW** deprecated the use, in such cases, of attic syringes. He had seen ossiculectomy very skilfully performed, but he did not agree with it, owing to the danger of lighting up latent foci of disease.

Mr. E. D. **DAVIS** referred to cases of chronic attic suppuration, generally met with in old people whose only symptom was discharge. On opening these the disease was usually seen to be confined to the attic, yet probably these patients got progressively deaf and had some intracranial complication.

Mr. **HUNTER TOD** objected to the sweeping condemnation of ossiculectomy, though he agreed it should only be carried out after grave consideration. It was by no means an unjustifiable procedure. Some years ago he published a series of 50 cases in which the operation had been done. As many as possible were subsequently followed up, but only three came back to have the mastoid operation performed. One died. He warned each of the patients that they might need a more thorough operation if symptoms returned. In some there was merely a suppuration in the mucous membrane, and for these ossiculectomy seemed to suffice. He discussed the matter in some detail, and particularised some successful cases.

Mr. J. F. **O'MALLEY** felt, with Mr. Cheatle, that mere removal of the ossicles was not likely to get rid of the whole of the disease in the kind of case described by the President.

Dr. W. **HILL** said his experience of ossiculectomy had been varied; in some cases he felt it had not been enough, in others he had been well pleased with the results. He had not practised it during the last five years, and did not think it should be by any means a routine.

Dr. **DUNDAS GRANT** considered that ossiculectomy certainly had its place in aural surgery. But when, as in Mr. Tilley's case, deep pressure over the antrum caused pain, that was a reason for not being content with ossiculectomy. He reminded members of cases of cholesteatoma, vertigo, and headache he had shown before the section in which mere ossiculectomy permanently cured the condition.

Dr. W. H. **KELSON** thought the pendulum had swung too far in the direction of operation for slight symptoms, such as discharge from the ear and but little else, and that many would get well under simple non-operative treatment. He had seen it stated in a book which posed as an authority on aural practice that such things as spirit drops and peroxide could not possibly cure chronic suppuration—the kind of untrue statement which should never be made.

Mr. **MARK HOVELL** agreed with Dr. Kelson, and spoke of the value of collosol argentum.

The **PRESIDENT** replied.

Bezold's Mastoiditis.

Mr. **O'MALLEY** showed a patient on whom he had operated for this condition. When seen the temperature was 101° F.; there was a swelling in the neck below the right ear and a free discharge from that ear, the mastoid being very tender. At the radical mastoid operation he found very extensive bone disease, extending through the tip of the mastoid into the abscess in the neck. There was also a peri-sinus abscess on the sinus wall, with masses of granulation tissue. Recovery was steady and uninterrupted.

The case was discussed by Dr. **GRANT**, Mr. **STUART-LOW**, Mr. L. **COLLEDGE**, the **PRESIDENT**, and Mr. W. M. **MOLLISON**.

Damage to Auditory and Destruction of Vestibular Nerve by Blow on Mastoid.

Mr. T. B. **LAYTON** showed a man, aged 33, who had been struck by a piece of shell on the right mastoid process. He had been deaf in the ear ever since. After being struck he was unconscious for two or three minutes, and continued for two months to have severe attacks of giddiness and headache. The tests carried out—which were detailed—showed that the vestibular nerve was destroyed and the auditory nerve partially so.

Several other cases were shown.

HUNTERIAN SOCIETY.

Modern Physiotherapy.

AT a meeting of this society, held on March 10th, at the School of Oriental Languages, the President, Dr. W. Langdon Brown, being in the chair, a paper was read by Dr. F. H. Humphris on Modern Physiotherapy. According to Dr. Humphris, this term includes treatment by all measures other than drugs, but he only had time to deal with three branches—the static wave current, diathermy, and radiotherapy. The most useful of the different currents derived from the static machine is that known as the wave current. The speaker described this current as appropriate for the treatment of almost every form of non-infective inflammation, acute or chronic, the presence of pus being a contra-indication. It acts by relieving congestion or stasis in conditions such as sprains, lumbago, neuritis, enlarged prostate, and so forth. Diathermy, or electro-thermic penetration, is an intensive form of high frequency. This current when passing through the body has no other effect than that of heat, and its value depends on the power to produce heat of any required intensity at any depth and within any part of the patient's body. Dr. Humphris described experiments made by him on pieces of steak and potatoes with diathermy, proving that the heat in the depth of the tissues is much greater than that on the surface. He then indicated the conditions for the therapeutic use of this current. These include a high blood pressure, and local lesions such as stiffened and painful joints, acute gout, migraine, neuritis, adhesions after abdominal operations, and disorders of menstruation. The surgical use of diathermy varies from the destruction of hæmorrhoids and papillomata of the bladder to that of rodent ulcers, nævi, or corns. X rays produce their effect in malignant disease by causing œdema of the endothelial lining of the blood-vessels, with subsequent occlusion of the artery, thus cutting off the nutrition of the growth; moreover, they have a special destructive action on new cells. X rays have proved useful for painful cicatricial tissue, non-suppurating tuberculous glands, keloids, exophthalmic goitre, uterine fibroids, induction of an artificial menopause, Hodgkin's disease, and various skin diseases. Dr. Humphris concluded an interesting paper by an estimate of the value of X rays in malignant disease and the conditions under which this treatment should be advised.—In the discussion which followed the President suggested that in eczema

X rays were used more for the pruritus than for the eczema itself. He agreed with Dr. Humphris's views on the value of X rays in the treatment of malignant disease.—Mr. J. Adams used it successfully in cases of malignant tongue unsuitable for surgery.—Sir H. E. Bruce Bruce-Porter testified to the good results he had seen obtained in the treatment of enlarged prostate, and asked Dr. Humphris to explain how it was that it arrested the frequency of micturition.—Sir James Purves Stewart also pointed out that a high blood pressure was not of necessity a matter for treatment.—Dr. Humphris, in reply to an inquiry by Dr. Adams as to how surgical diathermy acted behind the apparent sphere of action, said that the benevolent effects were due to the increased circulation set up in this region. Answering Dr. M. C. Corner, he said that as far as he knew this current had never been used in post-partum hæmorrhage. As regards the way in which frequency of micturition was reduced by the treatment of enlarged prostate, Dr. Humphris said that muscular contractions were induced, the gland tissue was compressed, the products of inflammation being squeezed out; a tonic circulation was then restored to the gland by the electrically stimulated cell activity. Each successive treatment gave more and more power to the muscular fibres, more tone to the glandular structure, leaving the gland smaller and of more normal consistence. Dr. Humphris was sure that Sir James Purves Stewart would admit that in many, though not in all, cases a lowering of high blood pressure was desirable. In diathermy we had a means of relieving the pathologically increased tension of the persistently contracted arterioles, and a simple therapeutic measure of approximating the blood pressure more nearly to the normal.

Dr. J. E. H. Roberts then gave an illustrated address on the Treatment of Septic Fingers.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Idiosyncrasy to Drugs.

AT a meeting of this society, held in the society's rooms at the West London Hospital on March 5th, with Mr. Herbert Chambers, the President, in the chair, a discussion took place on Idiosyncrasy to Drugs.—Sir William Hale White, who opened the discussion, said that many idiosyncrasies were apparent, not real. Apparent idiosyncrasies were sometimes to be explained by impurities in the drugs; at other times they depended upon varying composition of the drug. The best instance of inconstant composition was ergot, which contained varying proportions of at least three powerfully active bodies—ergotoxin, tyramine, and histamine. The solanaceous plants were another instance, containing as they did varying proportions of alkaloids. Delayed excretion of a drug, causing its action to be cumulative, might cause a person to appear peculiarly susceptible to the drug, whereas, in truth, he was not. Examples were digitalis, lead, and opium. Again, the rate of absorption of a drug might explain some instances of idiosyncrasy. All were familiar with the profuse erythema which occasionally followed the administration of a soap enema; this was believed to be due to the soap leading to the solution of a fæcal toxin. It was, the speaker considered, highly likely that variations in the intestinal contents might be the explanation of some cases of idiosyncrasy; for a drug, if it was usually slowly absorbed and soluble in the intestinal contents only with difficulty, might, from abnormal alterations of the fluids of the intestine, become readily soluble and therefore quickly absorbed. Or, again, the drug might, in the intestine, become chemically changed, and the changed drug be more soluble and easily absorbed, or have a different action and be readily poisonous. Apparent idiosyncrasies might, again, be caused by disease; for example, many cases of uræmia were benefited by morphia, yet, very rarely, the drug appeared to be a fatal poison. We were often disappointed in the relief of cardiac pain by nitrites; this might be because cardiac pain had a varying pathological origin. Passing on to the genuine idiosyncrasies, Sir William Hale White said that no attempt could be made, in the present state of our knowledge, to state the cause in the majority of the most important examples. The most remarkable were the iodides: ½ gr. daily for two days had caused iodism; on the other hand, he had given 300 gr. a day without any symptoms of it. Sometimes when the dose is diminished they will pass away; again, doubling the dose might lead to their disappearance. Cutaneous idiosyncrasies were manifested when drugs were applied externally or internally. He knew a nurse who was unable to put her hands into perchloride of mercury or handle mercurial gauze without getting general signs of mercurial poisoning. The selective action of lead, arsenic, and alcohol on nerves was most remarkable, and the explanation would be found, he thought, by the biochemist. The speaker concluded by alluding to the well-known idiosyncrasies manifested towards iodoform, veronal, camphor, tobacco, and alcohol.—Sir Robert Armstrong-Jones called attention to the familial record of alcohol, and to individual susceptibilities displayed towards pollens, aspirin, and sulphonal.—Mr. Bishop Harman narrated some cases of peculiar susceptibility to cocaine. One patient had a sharp attack of mania when cocaine was applied to the eye. Mr. Harman had also had recent experience of a case in which zinc sulphate drops, a grain to the ounce, had caused dilatation of the pupil and disturbed vision apparently through the accommodation. There was no defect of the eye itself, and the drops used were subsequently found to be innocuous with six other patients.—Dr. Halls Dally, speaking from experience in studying the effects of iodides in several hundreds of cases of tuberculosis under treatment by the intensive iodine method, considered the liability of iodism lessened in doses from 10 gr. upwards, and that if any given dose above 10 gr. gave rise to idiosyncrasy the remedy was to double the dose.—Dr. Vaughan Pendred mentioned a case in which less than ½ gr. of morphia had caused death from typical morphia poisoning in a healthy man aged 38.—Mr. P. A. Hendley, Dr. Seymour Taylor, Mr. F. G. Lloyd, and Mr. R. W. Lloyd also took part in the debate.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Irritable Heart Syndrome.

AT a meeting of this society, held on March 10th, papers on the irritable heart syndrome were read and discussed.—Dr. Carey Coombs, who dealt with the syndrome as seen in civil practice, gave an analysis of 50 cases. He said that in 90 per cent. there was no evidence of organic heart disease, and gave other reasons for regarding it as a nervous disturbance. About half the patients showed evidences of a temperamental predisposition. Physical effort was not a cause. Infections of various kinds, especially influenza, might be regarded as causal in 44 per cent. Distressing emotion of a protracted kind was apparently responsible for the onset of the symptoms in at least 36 cases.—Dr. C. E. K. Herapath outlined his experiences in a cardiac clinic of the Ministry of Pensions. Of his first 57 cases 9 were examples of various organic lesions: the rest were irritable heart cases. Among these 48 men there were 28 who dated their symptoms back to convalescence from some acute illness (influenza, trench fever, malaria, &c.). Of the remaining 20, there were 11 who ascribed the onset to some form of nervous disturbance. Dr. Herapath gave an account of his methods of investigation and treatment, laying particular stress on the value of optimistic "suggestion." He had, he said, already seen enough improvement take place to justify a further application of these principles.—Dr. A. G. Morris gave notes of cases of irritable heart in soldiers serving in this country, the condition developing without any infective or obvious cause, except anxiety as to the immediate future, which there was strong reason to regard as causal. He also described his experience on boards at an overseas base, which was to the same effect, that the "D.A.H." syndrome often sprang from pure "anxiety."—Dr. J. A. Birrell read notes of four cases of Severe Tachycardia following Influenza, in all of which the patients were under the influence of protracted anxieties at the time when the influenza attacked them. Analysis of this tachycardia had proved it to be of the supracardiac "nervous" type.—In the discussion which followed Dr. J. A. Nixon detailed experiences in France which led him to suspect infection of the heart itself as a cause of some of the tachycardias. He had seen post-mortem signs of early aortic syphilis, and also of an acute endocarditis of unknown origin in many men killed by wounding.—Dr. R. G. Gordon, on the other hand, supported the nervous theory. The kind of emotion that was most productive of this syndrome, he thought, was that expressed by the French "angoisse." He suggested that influenza allowed of the development of the syndrome with undue care, because of its action in diminishing higher-centre control of emotional expression.—Dr. D. A. Alexander suggested that functional disturbances set up organic disease.

WALSALL GENERAL HOSPITAL.—The fifty-sixth annual report of this institution, which covers the year 1919, shows that the annual income was £11,175, or an increase of £1428 on the previous year. The contributions of the workpeople of Walsall amounted to £2901. The expenditure was £14,768, and an appeal is made for greater public support. The number of in-patients treated during the year was 1282, and the out-patients 6971, with an attendance of 32,933. The number of operations on in-patients and out-patients respectively was 533 and 607.

Reviews and Notices of Books.

EXPERIMENTAL BACTERIOLOGY.

Die Experimentelle Bakteriologie und die Infektionskrankheiten, mit besonderer Berücksichtigung der Immunitätslehre. Ein Lehrbuch für Studierende, Aerzte, und Medizinalbeamte. By Dr. W. H. KOLLE, Direktor des Institutes für Experimentelle Therapie, Frankfurt a. Main; and Dr. H. HETSCH, Sanitätsdepartement des Kriegsministeriums in Berlin. Fifth edition. Abundantly illustrated. Berlin: Urban and Schwarzenberg. 1919. Vol. I., pp. 660, M.35; Vol. II., pp. 703, M.30.

THE present volume is an example of what can be done in the way of systematic exposition. It is impossible, however, to regard it as a text-book for English medical students, for its size would preclude its use by them. The physician and medical officer of health, the other two classes for whom the work is intended, are in a somewhat different case, but even they would probably use the book as a convenient and reliable work of reference rather than as a text-book. There is no doubt that for these the work is of considerable value, as it contains much information on the epidemiology and prophylaxis of infectious disease, and as to the relations which exist between laboratory investigations and the daily needs of the practising physician and health officer. The general plan followed is that common to most text-books; a little more than a third of the first volume is devoted to general considerations, and the rest to the characters and effects of individual organisms. The names of the authors are a sufficient guarantee that the work is well done.

The first part is the most distinctive. The authors devote themselves to questions relating to modes of infection and to the study of the various antibodies arising therefrom. The production of these antibodies, both in the laboratory and on a commercial scale, is fully set forth, and the use which is made of them in diagnosis and treatment is given in much detail. The book not being in any sense a laboratory manual the description of methods of demonstration and culture is relegated to an appendix. In the second part also the needs of the medical man and health officer are kept in view, and charts and maps are introduced for the better understanding of the epidemiology of the diseases treated. For these readers many of the excellent coloured plates will be of service, as they portray the clinical appearances as well as the pathology of the lesions.

Two editions have been produced since the commencement of the war, and a survey of the chapters on cholera, dysentery, and wound infection shows that much of the knowledge gained during this period has been incorporated, although in the case of gas œdema our own work seems to have gone farther than the German. The same is true with regard to the various spirochætoses which affected the armies in different parts of the world. In the use of vaccines for the preventive treatment of some of these diseases the Germans had greater opportunities than occurred on the western front, but on the whole there is a remarkable parallelism between the diseases common to the two armies, and in the researches made into their ætiology and methods of treatment or prevention. The results seem to have been very similar, and the chief difference lies in the names of the investigators to whom the advances in knowledge are attributed.

The book is well produced and is very well illustrated. The volumes sent for review are in paper covers.

PRACTICAL HINTS ON MINOR OPERATIONS.

By G. PERCIVAL MILLS. Birmingham: Cornish Bros., Ltd. 1920. Pp. 111. 5*s*.

"A PRACTICAL help for practical men, to enable them to do their minor surgery in a modern and efficient manner," is the aim of this little book of 111 pages. The author outlines concisely but clearly the treatment of inflammatory lesions, cutaneous tumours, minor deformities, foreign bodies in passages, hydrocele, varicocele, strangulated hernia, and retention of urine. There is also a useful chapter on local anæsthesia, and another on how to prepare for an aseptic operation in a private house.

A MANUAL OF MIDWIFERY.

Fifth edition. By THOMAS WATTS EDEN, M.D., C.M. Edin., F.R.C.P. Lond., F.R.C.S. Edin., Obstetric Physician and Lecturer on Midwifery and Gynæcology, Charing Cross Hospital, &c. London: J. and A. Churchill. 1919. With 5 plates and 369 illustrations in the text. Pp. 747. Price 24*s*.

IN the preparation of the fifth edition of this well-known text-book not much revision has been necessary. The sections dealing with the management of labour and the management of the infant have been re-written, and a considerable amount of new material in connexion with them has been added. The section on the management of labour is particularly good, and the author displays sound common-sense in his instructions to the student as to the methods he should adopt in the antiseptic treatment of these cases, more especially in regard to the advice he gives as to the occasions on which rubber gloves should be worn. The great importance of abdominal palpation is insisted upon, and these paragraphs are well illustrated. The section on p. 308 might be improved. The placenta cannot be said to fall into the cervix or the vagina. The level of the fundus really rises because the placenta passes into the lower uterine segment and ' the cervix, and so this portion of the uterus becomes enlarged and elongated as well as stretched transversely, which accounts for the suprapubic bulging of the belly wall. It is impossible for the placenta to be accommodated in the cervix alone, as the student might conclude from reading this section. The treatment of eclampsia is particularly fully dealt with, and the views of the two schools are well presented. We gather that the author, on the whole, favours the medical treatment of this condition as far as possible rather than the surgical, but he gives the arguments for and against the two methods sufficiently fully for the student to come to a conclusion on his own account. The administration of chloroform is now quite rightly condemned, and ether is recommended as the only general anæsthetic to be used. The section on the management of the infant is also good and clear, and full directions are given for the artificial feeding of the baby. In the treatment of constipation nothing is said of the great benefit of abdominal massage of the infant.

It is not necessary for us to say much of a book so well known as this, which has reached its fifth edition, and which is a universal favourite. The present edition has all the merits of its predecessors, and is well up to date.

ORGANIC CHEMISTRY.

By VICTOR VON RICHTER. Vol. I. Chemistry of the Aliphatic Series. Newly translated and revised from the German edition by PERCY E. SPIELMANN, Ph.D., B.Sc. Second (revised) edition. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1919. Pp. 720. 21*s*.

THIS well-known work is notable for its remarkable wealth of material. It may be consulted with the same confidence as a well-compiled dictionary, but, of course, the treatment of the subject is in proper group sequence. The volume is literally packed with the outstanding details in regard to the properties, preparation, and constitution of those substances included in the fatty series, while Volume II. of the work includes the chain or acyclic series. This new edition comes opportunely when the number of students of chemical science is rapidly increasing, attracted, no doubt, by the possibilities of wider applications of this field of study and research to industrial operations.

Principles and Practice of Physical Diagnosis.

By JOHN C. DA COSTA, jun., M.D., Ex-Associate Professor of Medicine, Jefferson Medical College, and Assistant Visiting Physician, Jefferson Hospital. Fourth edition. London and Philadelphia: W. B. Saunders Company. 1919. Pp. 602. 20*s.*

THE object of this work is to present within reasonable compass the principles of physical diagnosis, and to apply this means of research to the study of thoracic and abdominal disease. That these objects have been achieved is proved by the fact that a fourth edition has been called for. We believe that the book will be found useful for students just entering on their clinical studies, for ample consideration is given to clinical anatomy and to the origin, mechanism, and meaning of normal physical signs; whilst those students further advanced in the study and practice of medicine will find interest and instruction in the manner in which the subjects of pathology and diagnosis are dealt with, especially in regard to the examination of the circulatory system. There is a clear account of the electrocardiograph, and the deductions are given which may be drawn from electrocardiograms in various lesions of the myocardium and of the cardiac valves.

Some interesting remarks will be found on the functional capacity of the heart and the means of determining the state of cardiac force and of observing the effects of failing compensation. This is of importance in giving a prognosis in cases of cardiac disease in life assurance work, and in judging the capability of men for active work, such as recruits for the army. In the section dealing with diseases of the broncho-pulmonary system will be found sound observations on influenzal-pneumonia and hilus tuberculosis. Another subject appearing in this edition is a description of the methods of estimating intradural pressure, as in the operation of lumbar puncture.

There is a large amount of valuable information in the book: the observations are practical, and presented in terms which can be easily understood.

The Nursery School.

By MARGARET MCMILLAN. London: J. M. Dent and Sons, Ltd. 1919. Pp. 356. 7*s.* 6*d.*

Nursery Schools.

(Bale's Medical Books and Journals). 1920. Pp. 106. 5*s.*

IN spite of the protest which Miss Margaret McMillan makes in her preface, the nursery school is still in an experimental stage. The Education Act, 1918, has given education authorities the power to open and maintain nursery schools, and the Board of Education has stated the general principles under which it considers nursery schools should be run. The problem of the nursery school, however, is essentially different from the problem of the elementary school—even of the infant's department—as this is now conducted. Nevertheless the principles which should govern the nursery school are fundamentally the principles which should govern all school education—the cultivation of individuality, the development of health, the realisation to the full of potential mental efficiency, the socialisation of the individual whereby the right balance is secured between the claims of the individual for self-expression and the claims of the group for social efficiency. While these principles have not yet been assimilated by the majority of schools for older children, the nursery school movement has already recognised them. Consequently, there is a much greater gap between the elementary school method and the nursery school method, as contemplated, than there ought to be, and than there will be in the future. The nursery school is still in the hands of the pioneers, and pioneers are few. Its organisation, its method, its equipment, its staffing, are still under discussion. Out of all the discussion and experiment the well-organised nursery school will ultimately evolve itself. In the meantime, we must be very grateful for books such as these. Miss Margaret McMillan gives, in attractive and very sympathetic style, her actual experience in evolving an open-air nursery school in one of the London slums. It is an inspiring volume, characterised chiefly by its insight into child nature and its deep sympathy with the family life of the poor.

Messrs. Bale's publication does not pretend to be a consecutive study of the problem of the nursery school. It is a series of chapters written by various authors, each of whom has his own special contribution to make. The introduction to this volume is useful in that it goes straight for some of the precautions which must be taken to ensure "that the nursery school is not condemned in advance by sinning against the first laws of hygiene."

Hygiene and Public Health.

Second edition. By GEORGE M. PRICE, M.D. Philadelphia and New York: Lea and Febiger. 1919. Pp. 280.

THE second edition of this small book has been thoroughly revised. It contains an epitome of the more important aspects of hygiene and public health. A series of questions on the subject-matter discussed in the preceding pages appears at the end of each chapter. The book is obviously intended for the use of students or nurses preparing for examinations, and should prove useful in this respect.

Handbook of Sanitary Law.

By B. BURNETT HAM, M.D., D.P.H. Eighth edition, edited by HENRY R. KENWOOD, C.M.G., M.B., F.R.S. Edin., D.P.H. London: H. K. Lewis and Co., Ltd. 1920. Pp. xxiv. + 216. 5*s.*

THIS small book has long been popular among candidates preparing for the Diploma of Public Health. It is difficult for the average medical man to acquire even a rudimentary knowledge of the various Public Health Acts and other sanitary statutes, but in this little manual the law relating to public health is arranged and condensed under various headings which facilitate reference and assist the memory. The book, which was first published in 1899, is now in its eighth edition, and it is only necessary to add that it has been edited and thoroughly revised by Professor Kenwood to ensure for it as great, or possibly an even greater, success in the future than it has enjoyed in the past.

My Chess Career.

By J. R. CAPABLANCA. London: G. Bell and Sons. 1920. Pp. 212. 7*s.* 6*d.* net.

THE recent victory of Capablanca in the Hastings Victory Tournament and his many successful simultaneous displays in this country makes this book of peculiar interest to chess-players at the present time. It is in the form of a short biography in two parts, illustrated by 35 selected games. Part I. shows the gradual evolution of the author's chess powers from his first victory at the age of 12 over the Cuban champion Corzo until he reached his full maturity as a chess-player at the Petrograd Tournament, 1914. "Hereafter," he says, "I may gain a little from experience ...... but whatever I may gain in one way I am sure will show a corresponding loss somewhere else." Part II. represents his period of full development and includes two games from the Hastings Tournament. The games gain immensely by being annotated by himself, though some readers may find his frankness too complacent. These notes are very clear; moreover, they tell the average reader exactly what he wants to know without confusing him with unnecessarily abstruse analysis. Particularly interesting are those which deal with the game with Janowski in the San Sebastian Tournament and a game with Marshall, for which the latter had prepared a special variation of the Ruy Lopez. It would, perhaps, have been still more interesting if he had included some of his rare defeats among the collection of games, notably the game won by Rubinstein at San Sebastian and the games against Lasker at Petrograd. The latter would have had a particular interest in view of the forthcoming match for the world's championship.

HANDBOOK OF TUBERCULOSIS SCHEMES.

Second edition. Issued by the National Association for the Prevention of Tuberculosis. London: Adlard and Son and West Newman, Ltd. 1919. Pp. 164. 5*s*.

THE purpose of this handbook, the first edition of which was published in 1916, is the provision of an index to the progress of the campaign against tuberculosis in the United Kingdom, with the further object of stimulating increased effort in its prosecution. It has now been brought up to date, and, moreover, includes a valuable alphabetical list of residential institutions, official and voluntary, for the indoor treatment of tuberculosis. The information given is conveniently arranged under the same pattern of parallel headings for counties in the first part of the handbook, and for boroughs in the second part. Comparison is thus made easy; moreover, the presence or absence of arrangements under each heading is definitely stated, or the fact that no information is available is indicated. The clear and useful nature of the handbook will be evident from the page which we here reproduce in full:—

Norfolk.

Area.—1,303,570 acres. *Population* (Civil).—281,616.

Character.—Rural.

Industries.—Chiefly Agriculture.

Deaths from Tuberculosis.—Pulmonary 337 } 421.
Non-pulmonary 84 }

Death-rate from Pulmonary Tuberculosis (per 100,000 civilians living).—119·7.

Tuberculosis Dispensaries.—Under consideration. Not yet opened.

Sanatorium.—Pulmonary: Kelling Sanatorium, Holt, 100 beds. Non-pulmonary: Norfolk and Norwich Hospital, Norwich; Jenny Lind Hospital, Norwich; Lord Mayor Treloar's Cripples' Hospital, Alton, Hants. Beds as required.

Farm Colony.—Graduated out-door work done at Kelling. B.R.C.S. have given £17,000 to start a Farm Colony.

Open-air School.—None. Most schools in county have open-air classes.

Hospital (advanced acute cases).—None. Patients taken at a few Poor-law Infirmaries, 8 beds.

Care Committees.—To be formed.

Medical Staff.—(*a*) Chief administrative officer: J. T. C. Nash, M.D., D.P.H., county medical officer. (*b*) Tuberculosis officers: Not yet appointed. F. W. Burton-Fanning, M.D., F.R.C.P., has been acting as consulting officer to the Insurance Committee.

The handbook forms a work of reference that will be appreciated by a wide circle of people interested in the problem of preventive medicine.

JOURNALS.

Journal of Pathology and Bacteriology. Vol. XXIII., No. 2. Pp. 129–240.—The Bacteriological Characteristics of Tubercle Bacilli from Different Kinds of Human Tuberculosis, by A. S. Griffith.[1] Serological Groupings of *Vibrion septique* and their Relation to the Production of Toxin, by Muriel Robertson. The various strains of this important pathogenic anaerobe can be classed into at least three groups by agglutination tests. Toxin is rapidly (24–48 hours) developed in liquid cultures of the correct reaction and antitoxic sera can be readily made. Antitoxin made with a single strain will neutralise the toxins from cultures belonging to each of the three agglutination groups.—An Inagglutinable Strain of Shiga's Dysentery Bacillus, by T. H. C. Benians. From a chronic inflammatary lesion produced in a guinea-pig by the inoculation of Shiga's bacillus the author isolated an organism identical in every way except that it would not agglutinate, absorb agglutinin, or act as an agglutinogen; but it threw off from time to time strains which were normal in these respects. Method of Determining Viscosities, Determination of Specific Gravity by the Viscometer, Method of Testing Temperature Sense, Methods of Anaerobic Culture, by J. Holker. Useful laboratory tips.—Streptococcal Ulcerative Endocarditis of the Aortic Valves in an Infant aged Six Months, by J. H. Dible.—The Classification of Forty-eight Strains of Flexner Y and Allied Bacilli Mainly by Serological Tests, by E. M. Berridge and E. E. Glynn. The groupings found correspond roughly with those determined in other inquiries; there is no correlation between serological and fermentative reactions in the subgroups.—Agglutination in Bacillary Dysentery, by J. W. McLeod and A. G. Ritchie. Freshly made emulsions of dysentery bacilli react more with the sera of infected persons and less with those of normal people than old emulsions, and hence are more useful in diagnosis.—The Synthesis of Tryptophane by Certain Bacteria and the Nature of the Indole Reaction, by W. J. Logie. Certain strains of *Bacillus coli* and *B. Friedländer* can grow in proteid-free media and synthesise tryptophane; this capacity to make a ring compound corresponds with their vegetable nature. Indole "formation," as ordinarily understood, is a consequence of a diminished use of indole as tryptophane rather than a special formation.—The Absorption of Dyes and Inorganic Salts by Solutions of Lecithin, by J. Cruickshank. Lecithin in ethereal solution extracts dyes and some salts from watery solutions; fats, fatty acids, soaps, and cholesterin do not act in the same way. The dye acquires the solubility of a lipoid while retaining its original colour.—The Gold Sol Test of the Spinal Fluid, by J. Cruickshank. Practically useful, but many experiments leave it still an empirical test.—Preliminary Observations on the Physics of the Wassermann Reaction, by J. Holker. The rate of development of turbidity on mixing inactivated serum with guinea-pig-heart-cholesterin antigen differs in normal and syphilitic sera.—Adenomyoma Involving the Ileum, by Clara Stewart. A tumour of apparently uterine origin.—Some Technical Points Relative to the Investigation of Variability among Bacteria, by A. E. Boycott.—The Killing of Tadpoles by Heat, by A. E. Boycott. The results are in accordance with a distribution of resistances on the normal curve.—A Case of Polycythæmia Rubra, by W. E. Hume and A. F. B. Shaw. A full anatomical and histological account of a fatal case of splenomegalic polycythæmia.

Edinburgh Medical Journal. Vol. XXIV., No. 3. Edinburgh: Oliver and Boyd. London: 33, Paternoster-row. Monthly, 3*s*.; annual subscription, 30*s*.—Since the New Year this valuable monthly journal has been appearing in a new garb. Among the four original articles in the issue for March is a paper by Mr. James M. Graham on Transfusion of Blood in Cases of Hæmorrhage, which is a distinct contribution to our knowledge of the type of case in which blood transfusion can be applied with advantage. Mr. Graham has proved by direct experiment on dogs the immense gain that is made by using blood instead of saline solution in cases of extreme exsanguination, and the experience of the war has provided ample evidence that the same principle is clinically applicable. The field for blood transfusion in civil practice remains yet to be explored, and Mr. Graham has made an interesting beginning with the 12 cases that he records. These include melæna neonatorum, hæmorrhage from gastric ulcer, hæmorrhage and shock following ruptured ectopic gestation, and several cases of secondary hæmorrhage following operation. As Mr. Graham points out, there is probably an exceedingly useful application for blood transfusion in cases of prolonged slow hæmorrhage from a gastric or duodenal ulcer, since it is becoming evident that the hæmorrhage tends to be arrested rather than encouraged by transfusion. Mr. Graham's records do not include a case of hæmophilia, but the effects, as he anticipates, would certainly be comparable to the very good result obtained by him in a case of melæna neonatorum. He has used transfusion in two cases of purpura hæmorrhagica, but is not yet willing to express an opinion on the value of the process in this disease. The same issue contains a clinical note by Dr. B. Soutar Simpson on a remarkable case of Diffuse Hypertrophy of the Breasts, and a critical review of a very searching character by Dr. J. S. Fraser on the Vestibular Apparatus.

IN the review of Bonney and Berkeley's "Guide to Gynæcology," which appeared on March 13th, the price of the work was given as 31*s*. We are asked to state that this book was published at 31*s*. 6*d*. net.

THE LANCET.

LONDON: SATURDAY, MARCH 27, 1920.

The London Voluntary Hospitals.

It is notorious that the problems of London, in all matters of social administration and development, are different from those that present themselves in areas not so immense. Centres of population that are less artificially separated into widely differing sections of wealth, status, and occupation more readily conform to general schemes, and for that reason the position of London, in respect of the voluntary hospitals, cannot be regarded as typical of what may prevail elsewhere. But at a time when the pecuniary position of all these charitable institutions is the subject of the gravest anxiety, the circumstances in the metropolis have an interest for the whole country. A statement has been issued by King Edward's Hospital Fund for London on the present position of the London voluntary hospitals, setting out the nature of the problem which has to be faced to bring these institutions back to a level of solvency, and in this way showing that the impression of hopelessness, which might well have been derived from many of the public pronouncements on the situation, has not been warranted. Ominous the general position may be, but it is not desperate; and the message to be derived from an important document is that all precipitate meddling would be unfortunate and that the arousing of the public conscience is the first need.

The calculations of those responsible for the distribution of King Edward's Hospital Fund are necessarily based each year on the figures dealing with the previous year, but from the surplus, deficits, and debts thus shown it is possible to make a rough summary of the general position of any institution or of a whole group. At the beginning of the war it was anticipated that the voluntary hospitals would be faced with immediate financial difficulties from increased prices and decreased contributions; but the reverse occurred, and the crisis then expected has been postponed until now. The statement of the Fund shows that 1913 was a good year and 1914 a moderately good year, so that the money in hand from the period before the war could be used after the commencement of war, and could be eked out by a general postponement of building schemes. The next four years were all unpromising from a financial point of view for the London voluntary hospitals; 1915 was a distinctly bad year, while prices had now begun to rise in a threatening manner. But the hospitals were during this period obtaining War Office payments for the beds occupied by soldiers, so that it was not until 1918, when these payments ceased, while prices continued to rise, that the pinch began to be badly felt. In view of the results of 1913 and 1914, the King's Fund decided not to distribute money saved by the suspension of building schemes or received from large legacies or other exceptional windfalls, until it was known to what extent the hospitals would be affected and which hospitals would need help most. The amounts actually distributed, on this basis, were as follows: In 1913 the Fund distributed £157,500; in 1914, £140,000; in 1915, £140,000; in 1916, £170,000; in 1917, £190,000; in 1918, £200,000; in 1919, £230,000. The increased distribution in 1919 was due to the fact that the total was based, not only on the figures for 1918, the last year of the war, but also partly on the anticipated post-war needs of the hospitals, especially the necessity of carrying out deferred renewals and repairs. To effect this increase the Fund had to draw to the extent of about £46,000 on the reserves created during the war by exceptional legacies. The figures for 1919 are not yet complete, but the statement indicates that the year will end with a net deficiency of about £210,000 on a total annual expenditure of rather more than £2,100,000; that is to say, that with doubled general expenses, vast increases in the cost of therapeutic measures, and heavy additions to the numbers of beds, the voluntary hospitals were still able to meet out of their income for the year, including grants from the central funds, 90 per cent. of their bill.

Why, then, should voluntary hospitals not be continued as such, for a considerable period at any rate, if after the ordeal of the war the pecuniary position is so little worse than previously? These hospitals, the gift of those who have to those who have not, with a great past behind them, possess a future of beneficent work, if only they receive adequate support from all able to give. Those who give are rewarded by the consciousness of their good deeds, and those that receive—the hospital patients—know that the first qualification is their physical need of aid, and the second their poverty. Patients may slip in who would be excluded if an inquisitorial examination of their means were to be instituted; and this we are far from demanding, for the knowledge that details of private life will be minutely examined might deter many, genuinely qualified by poverty as well as by sickness, from applying to the voluntary hospital. The question would appear, therefore, to be whether an increase of institutional treatment, under State ægis, for patients qualified by insurance or by the payment of fees within their means, may not be possible side by side with charity for those who can make no contribution. Until we are reasonably certain that a better scheme has been devised to take its place the voluntary system must hold good, as far as London is concerned, supplemented, but not supplanted, by public funds. The voluntary side can be relieved of persons whose means render them better suited for treatment elsewhere, or the hospitals can be subsidised within limits without being deprived of their independence of control. The manual workman of the future, enjoying as a class higher wages than heretofore in proportion to the price of necessaries, may not be a fitting object of charitable aid; for the moment he is hardly in that position. In view of his contributions in bulk he may regard himself as paying his way to the full, but that is an error in arithmetic; while there will always be among us a proportion of our fellow-subjects for whom hospital treatment in times of severe injury or sickness will be in fact charitable aid. From the combined generosity of the prosperous citizen and the medical profession has emerged the voluntary hospital; if the partnership is to be dissolved by the enforced retirement of the citizen his partners cannot be expected to carry on as the only voluntary workers. This contingency, it appears, can be for the time avoided in the metropolis by an increase of rather more than 10 per cent. of subscriptions, which ought to be promptly forthcoming.

Gastric Ulcer and the Surgeon.

GASTRO-INTESTINAL affections are among the commonest of the ills which affect the community and anything which can be done to diminish them will be a great boon. Gastric surgery has barely come of age, but the last ten years have shown a rapid growth in appreciation of the character of the disorders for which surgical interference is in place. This is well seen in Mr. JAMES SHERREN'S Hunterian lecture, which appears in our present issue, and in the discussion on the Remote Effects of the Surgical Treatment of Gastric and Duodenal Ulcers at the Surgical Section of the Royal Society of Medicine, reported at length in THE LANCET of March 13th. Until comparatively recent times the only surgical treatment offered for an ulcer of the stomach or duodenum, which defied medical treatment, was gastro-enterostomy. This operation, after being praised to the skies, was found to give rise to many failures, and fell into disrepute. In the series of cases now reviewed by Mr. SHERREN the proportion of definite cures is high, and it will be instructive to inquire into the reasons for this advance.

The first improvement lies in the proper selection of cases for operation, inasmuch as bad results are due more to injudicious selection of cases than to errors of technique. Help in this direction comes from improved methods of diagnosis, in particular from the chemical analysis of the stomach contents, which we owe to the physiologist. More, we hope, remains to be learned from the chemistry of the secretions, and the trust is not misplaced that, with greater understanding, the evils we now labour to cure by operation may be prevented by medical and dietetic means. The second line of advance lies in improved technique, in order to avoid the ill-effects which were found to follow the operation of gastro-enterostomy in its early days—namely, regurgitant vomiting, peptic ulcer, and stricture. Mr. SHERREN rightly points out the value of a wait-and-see procedure; in any individual case the operation required can only be exactly determined after the abdomen is opened. Gastro-jejunostomy is still the operation of choice in the majority of cases, and this alone will bring about the permanent healing of ulcers which are not adherent. Ulcers which have perforated and become attached to the liver or pancreas do not heal completely after a simple short circuiting, and for these cases a partial gastrectomy is required. Mr. SHERREN tells us that the troublesome stricture of a gastro-jejunostomy opening is now known to be due to marginal ulceration following the use of unabsorbable suture material, and can be abolished by the substitution of catgut for silk or thread. The opening should be large, not less than 2½ by 3½ inches, and should be situated at the cardiac end of the pyloric segment of the stomach, immediately above the duodeno-jejunal flexure. This position has the effect of lowering acidity which along with chronic stasis is the chief cause of chronic ulcers. Secondary jejunal ulcer may be prevented by avoiding the use of a jejunal clamp, which bruises the mucous membrane of the jejunum, and by attention to after-treatment. Should the post-operative test-meal show a high acidity, dietetic treatment should be directed towards reducing it.

In taking stock of our knowledge of affections of the stomach and the methods of cure at our disposal, it is abundantly clear that we still have much to learn. Further, it appears that the problem is largely one for the chemist and physiologist. With them the surgeon should not fail to take counsel.

Military and Civil Hygiene.

THERE is something piquant attaching to the delivery of the Chadwick lectures by a Director-General of Army Medical Service, for the contrast is in this way brought out between the hygienic administration of the whole community and that of a disciplined service. CHADWICK'S long life was spent in the cause of civilian hygiene, and if there is anything more clear than another it is that the practice of hygiene in a civilian community cannot be imposed by edict of a Ministry of Health, even when such exists. The health of the civilian community can only be built up on the basis of individual enlightenment in regard to the principles and practice of personal and family hygiene, and it will be complete when the knowledge of the proper use of fire, air, earth, and water has covered the land. Sanitary authorities can, if they will, make it easy for this knowledge to be disseminated in practical and efficient channels. The civic life of the community and the public services run by it may be object-lessons for the individual citizens, but the ignorant, the prejudiced, and the selfish man will continue able to spoil the hygienic circumstances of his own life and those of his neighbours and relatives. Education is, as the late Sir Robert Morant saw with prophetic clearness, the chief and in the final issue the only effective instrument of civil hygiene.

Military hygiene, with aims and objects precisely similar, has a different discipline. The Army, as Sir John Goodwin puts it, is fortunate in possessing a disciplined populace and a perfected organisation which permits of action for the community as easily as for the individual. This is the strong position of military hygiene. Given the knowledge of what is to be attained, and how it may best be attained, there seems no limit to attainment, the instruction descending from the director-general to deputy after deputy until it is transmitted into action by the privates of the sanitary staff. For this reason, and Chadwick would have been the first to admit it, military hygiene has made progress vastly greater than civilian hygiene, as is abundantly clear from two very able summaries of Past and Present Hygiene given by Sir John Goodwin, of which abstracts have already appeared in our columns. The success achieved is of a very high order, the most striking figures, perhaps, being those of sickness and mortality-rates among European troops serving in India in the years 1878/82 and 1912 respectively, the death-rate at the later period being 1/20 of that at the earlier. There are some who hold that the results might be even better were the director-general of Army Medical Services made master in his own house and not subservient to an adjutant-general. It appears anomalous that a branch of the services which has shown marked improvement in modern warfare should not have a seat on the Army Council, and there was considerable force in Colonel Fremantle's presentation of this point in the House of Commons last Monday, in which he was ably supported by Captain Elliot.

Sir John Goodwin's last lecture, which we print in abstract this week, takes a dip into the future, and we may consider with him how the lessons of the army surgeon are to be used for the civilian community. It is no small achievement that military and civil hygiene should have been brought together, and evidently it is desirable for them to continue to work in harness. In billeting there is one hygienic problem with two aspects, for when a military guest is billeted on a civilian host, the army has to protect itself by cleaning up local infections among the general population. Perhaps the most urgent and timely hygienic lesson of the war is the efficacy of simple materials used in an intelligent way. The lives of regiments were saved by the use of empty tins which a local sanitary authority would have consigned to the refuse heap. Our civil authorities have to learn that as much can be achieved with simple materials —mixed, as Opie would have said, with brains—as by the use of complicated engines of hygiene. Small sanitary authorities, knowing nothing but their inability to afford costly apparatus, should be roused to action. They will now have at their disposal many discharged soldiers who have been members of the Army Sanitary Staff, and many more householders who have been drilled year-in year-out in the elements of hygiene by diligent regimental officers. This sometime thankless work should yet bear fruit in a healthy countryside.

Annotations.

"Ne quid nimis."

THE RE-EDUCATION OF MOVEMENT.

Few can have realised the difficult psychological problems involved in restoring perfect function to the man deprived by accident of the normal use of one or more of his limbs. In the discussion on the Re-education of the Amputated at the Medical Society of London on Monday evening last Mr. V. Warren Low, who presided, emphasised the rapid mental deterioration which he had long noted in civilian amputees who did not, at the earliest possible moment, resume their previous employment. At Roehampton, Mr. Muirhead Little stated in his instructive introductory address, 46 per cent. of military amputees were able after training to resume their civilian occupation, and another 21 per cent. to take up some active life. The remainder, an exact third of the whole, were referred back to their local pensions committees, and presumably mental deterioration was present in many of these. Jules Amar showed experimentally that 80 per cent. of disablement could be removed by the timely application of appropriate means. In the early years of the war re-education was largely a failure in this country, not on account of the badness of the material, but because the methods for dealing with it had not then been worked out. Soul-destroying mechanical movements were used to restore function, until it came to be realised that, as in primary education, it was essential to secure the interest of the pupil, and this implied purposive effort. Sir William Robertson, witnessing the performance of exercises designed to strengthen the climbing muscles, said, why not climb? And the principle has been successfully extended without limit. Mimicry is probably only part of the explanation. Sir Arthur Pearson found that the blind man was the best instructor for the blind; contrary to scripture, he did not lead him into the ditch. And now in the orthopædic centres mutilated instructors impart the principles of their own success to those similarly mutilated. The rôle of Captain R. Maxwell, chief arm instructor to the Ministry of Pensions, as a sort of mannequin for artificial arms—he can wear and use more than 20 varieties—has marked a further epoch in re-educative methods. The full report of this meeting will afford interesting reading.

SURGICAL APPROACH TO THE UPPER ABDOMEN.

Fear of opening the thorax and, in so doing, of upsetting the mechanism of respiration has prevented thoracic surgery from making the advances seen in the operative treatment of the peritoneal cavity and its contents. This fear was largely responsible for the policy of non-intervention in cases of gunshot wounds of the chest during the early years of the war. Prior to the war it was thought necessary, in order to open the pleural cavity without danger, to employ some form of pressure chamber to avoid the collapse of the lung. Pressure chambers are cumbrous and expensive. It was impossible to use them on any considerable scale in the field. But army surgeons, forced to operate without their aid, soon found, to their surprise and relief, that they could do so with safety. MM. A. Schwartz and J. Quénu, in an article[1] entitled Chirurgie de la Zone Frontière Thoraco-Abdominale, point out to their French colleagues that the pneumothorax produced by operation does not constitute a serious risk nor one which should deter surgeons from using the thoracic route when it offers the best access to their objective. Direct access to the structures immediately below the diaphragm is impeded not so much by the costal arches as by the potential pleural spaces which extend down between ribs and diaphragm. The risk of infecting the pleura should not be a deterrent, for precautions should be taken to prevent it occurring. Based on this essential principle, Schwartz and Quénu have planned trans-pleural and trans-diaphragmatic operations for exposing and dealing with diaphragmatic hernia, affections of the upper surface of the liver on the right side, and with the cardiac end of the stomach and the spleen on the left side. They make the claim that this route gives better exposure than can be obtained by the incision of an ordinary laparotomy. The article is suggestive and worthy of consideration.

SCIENTIFIC DIGESTS.

"IF the space occupied by a subject in German medical literature were any criterion of its importance, the partial antigens of the tubercle bacillus separated by the Deycke-Much method would claim considerable priority ...... no final judgment can be presented either on the theory or the practice of the Deycke-Much system until more confirmatory work has been done."

These lines, taken from *Medical Science* for March, give an inkling of the difficulties and tediousness of the task which the Medical Research Committee has set itself in publishing a monthly summary of current medical literature. Of the thousands of medical papers published annually only a fraction represents new and interesting work. Shortly before the outbreak of war Professor Penzoldt, that great clinician whose recent seventieth birthday celebration evoked sympathetic interest outside his fatherland, presiding at a medical congress at Wiesbaden, appealed to his colleagues to confine their publications to brief accounts of new and important matter. He was not particularly successful. Naturally, no one pleads guilty to the reckless tautology of a parrot; and it is but human to believe that, whatever tares others may sow, one's own products can be nothing but good seed. Hence the need for a sorting house, for a "Centralblatt," and still more for a sheaf of "Centralblätter," as *Medical Science* may well be described. As each section is edited by a specialist the digests gain in value by the running editorial commentaries with which several of them are punctuated. There is a natural tendency to deal with laboratory rather than purely clinical matter, and this is the less to be regretted as the *Medical Review*, under the able editorship of Dr. J. T. Conner, already supplies a monthly record of new clinical work quarried from many sources. Since the first appearance last October of *Medical Science* a valuable addition has been made of a section devoted to biochemistry under the editorial supervision of Dr. C. G. L. Wolf. All the sections show signs of fastidious discrimination, though there are wide differences in the handling of their material by the various editors. It would be invidious to distinguish between them; their team-work is all the more valuable for not being cramped by a rigid system. The two-line as well as the two-page abstract has its patrons, but we are glad to see that the two-word review has not found favour. It is wiser to ignore altogether publications of little or no value.

RUBBER BANDS AS A SUBSTITUTE FOR LIGATURES.

IN the *New York Medical Journal* of Jan. 17th Dr. A. L. Soresi has advocated the use of small rubber bands for hæmostasis instead of ligatures. His method is as follows. The nurse prepares artery forceps for use by slipping over them the rubber bands. The forceps are boiled, care being taken that they are not boiled so long as to impair the resiliency of the rubber. In operating the surgeon catches the blood-vessel or tissues in the usual way. He then slips the band over the blood-vessel or tissues by means of a thumb forceps; this avoids the use of the fingers and possible infection therefrom. With a little practice this operation can be done so rapidly that the surgeon will find it advantageous to remove the forceps immediately instead of at the end of the operation, and so to prevent any inconvenience caused by their presence. It is recommended that several bands be placed on each forceps. Dr. Soresi holds that rubber bands are preferable to ligatures except when the ligature may become the centre of a calculus, as in the bladder, whether the ligature is absorbable or not. He claims the following advantages. Rubber bands are safer than ligatures, because there is no danger of late hæmorrhage, due to the possible slipping of knots or the cutting of the tissues. There is no danger of hæmorrhage from an imperfect ligature, such as loose knots or the slipping of the ligature while it is being tied. The rubber band immediately and securely grasps the tissues. It does not cut the tissues, because its action is not due, like that of the ligature, to the tightness with which an inelastic thread is drawn, but to the resiliency of the rubber. It cannot slip when being applied, because the forceps cannot be removed easily until the band is beyond the tips of its blades which are holding the tissues. It does not slip afterwards because the tissues immediately assume the form of figure of eight, the groove in the "eight" being made by the compression of the tissues. Further, it produces a mild irritation of the compressed tissues, which helps in securing its stability. It can be applied much more rapidly than the ligature. Even when the point of hæmostasis is deep the band can easily be applied. It is better tolerated by the tissues than catgut, silk, or other material used in ligatures. The possibility inherent in all ligatures of the ends acting as setons is removed. As the band is never touched by the fingers after sterilisation this source of infection is abolished. Because of the gentler action of the band the tissues beyond preserve a certain vitality and are not condemned to rapid death and sloughing, as they are when the ligature is used. This is important in abdominal surgery, in which the dead tissues beyond the ligatures become the centre of adhesions. Moreover, the death of the tissues beyond the ligature facilitates infection. Rubber bands are much cheaper than ligatures.

---

[1] Paris Médicale, Feb. 21st.

Such are Dr. Soresi's claims; up to the present he has used rubber bands only where largish blood-vessels were in question. His results he records as good.

STANDARD CONDENSED MILK.

THE appointment of an Interdepartmental Committee by the Ministry of Health to consider the question of a standard composition for condensed milk is of importance, since there is a large demand for this food product, and whatever else may be said about this process of preservation, at least it saves a large quantity of milk, appreciated by a considerable section of the community. Its high nutritive value cannot be disputed. The question of standardisation presents difficulty, as the composition of the original milk is variable, and the ultimate composition of the concentrated product obviously depends upon the length to which the condensation is carried. A guarantee could, of course, be founded on minimal limits in regard to percentages of constituents, and particularly fat, condensed milk being largely used for infant feeding. Correct dilution again depends upon the degree of concentration, and if a system of labelling be introduced the directions in this regard should be accurate. But a label setting forth an analysis of the contents of the tin would convey little meaning to the public and it is doubtful whether manufacturers could certify exactly the composition of every consignment they sent out. After all, the main thing is to secure that the consumer gets an article of the "nature, substance, and quality demanded," to quote Clause 6 of the Sale of Food and Drugs Act.

THE FATE OF THE FEEBLE-MINDED.

WITH the best intentions the various agencies concerned with the care of mentally defective persons continually get in each other's way and expend their energies in antagonistic efforts. Narrow views are taken because only one aspect of the matter is studied. Voluntary workers are impatient of the restrictions imposed by the Legislature; public officials of all grades forget that "the letter killeth"; judicial authorities hold divergent views about national policy and their functions in furthering it. Especially in regard to the need for interference with individual liberty is there discord. One body of public opinion considers it a matter for congratulation when for any reason attempts to obtain or maintain control of defectives break down, while another resists with all possible vigour any effort to remove such persons from institution care. In both cases the limitations of our knowledge are primarily responsible for the difficulty. Valuable information bearing upon the subject is to be found in a paper by Dr. Walter Fernald,[1] the widely known director of the Massachusetts School for the Feeble-Minded, who has recently collected particulars of the fate of the patients discharged from that institution during a period of 25 years. Of 1537 persons discharged he has been able to follow up the history of 646. Stated summarily, his results show that of 470 males 250, however profitless they might be to the community, did not in fact constitute any serious menace to it. Of the remainder 54 had died, 68 had been readmitted to Waverley, 23 had been arrested for crimes or misdemeanours, and 75 had been committed to various institutions. 176 female patients were traced, of whom 24 had died, 33 had been readmitted to Waverley, and 29 had been committed to other institutions. 52 of the remaining 90 "are apparently giving no trouble," and of these 11 are married and are "living useful and blameless lives," while 8 unmarried women are "self-supporting and self-controlling." Naturally the patients who are doing satisfactorily are those presenting the slighter degrees of mental defect. These results should, as Dr. Fernald says, "be interpreted with great caution," but they suggest that the beneficial effects of institution care may be more permanent than some experienced workers among the mentally defective have supposed likely.

THE WHEREABOUTS OF ENTERIC CARRIERS.

ENTERIC fever is now an exceptional disease in London and most county boroughs. It still prevails in many of the smaller sanitary areas, and in 1917 caused 977 deaths. The two chief endemic sources are shell-fish and carrier cases, and the latter are probably the source of most of the outbreaks that now occur. In the *Medical Officer* for Feb. 7th Dr. E. Lewis-Lloyd, medical officer of health of Merionethshire, reports an outbreak comprising 23 cases occurring at Towyn from 1909–1918. Water-supply, sanitation, and other possible causes having been excluded, the source was finally traced to milk provided by one farm. Although local regulations required the cleansing of the cows' teats and udders and the hands of milkers, it was found that both these practices were habitually neglected. The four milkers were examined by the Widal test and two gave a positive reaction, although neither was known to have suffered from enteric fever. The fæces and urine of the two positive cases were then examined for typhoid bacilli and these were found in one case, who was thus shown to be the innocent cause of the outbreak. We are assured that steps have been taken to prevent further danger from this source, and it is to be hoped that these include such provision as will make it improbable that the infected milker will ever again be engaged in the production of human food. Such persons require to be treated as suspects for life, or until, at least, three successive bacteriological examinations at prolonged intervals have shown their freedom from infection. That is the present rather hopeless position in regard to carriers, although work such as that of Dr. J. W. Brownlie on diphtheria convalescents, given on p. 706 of this issue, affords at least a prospect of radical cure. As most health departments do not possess a staff adequate for supervising the movements of suspected persons, it seems desirable that the police should undertake this duty and report any change of address to the medical officer of health. An instance occurred not long ago in an eastern county where a carrier, whose dangerous propensities had just been established by an enterprising medical officer of health, forsook the neighbourhood, leaving no address. But although hygienically criminal the carrier deserves every consideration for what, after all, is morally an innocent failing. Should there be any question of difficulty in obtaining suitable work, he should certainly be allowed sufficient pecuniary assistance to make it unnecessary for him to return to his former occupation. The Ministry of Health might well keep a record of all carrier cases and require a yearly report on the condition and occupation of each.

[1] After-care Study of the Patients Discharged from Waverley for a Period of 25 Years. By Walter E. Fernald, M.D. Ungraded. Vol. v., No. 2, November, 1919.

THE CHEMOTHERAPY OF THE PHENOLOLIPOIDS.

THE search for substances which, like therapeutic serums, have a specific elective action in infective diseases has given rise to the important branch of chemotherapy in the field of experimental therapeutics with its successful results in protozoal diseases. Similar trials have been made in certain bacterial diseases for which a definite immunotherapy is not yet discovered. Chemotherapy, however, has an original defect in its application to bacterial diseases in general, for such substances besides being parasitotropic are also organotropic, and only those could be used as drugs which possess these two properties in due proportion. Hence it is necessary to find substances which are feeble in organotropism and strong in parasitotropism, and which, moreover, have the possibility of counteracting the effects of the toxæmia caused by the infection itself; in other words, they should be antibacteric and antitoxic at the same time, like the therapeutic serums. This problem has stimulated the experiments of Dr. Cesare Piazza, of Palermo, who publishes his results in a recent number of the *Annali di Clinica Medica*.[1] He turned his attention, on the one hand, to phenol, well known for its parasitotropic and organotropic action, and, on the other, to the various normal lipoid constituents of the living organism, the antitoxic action of which has been established by numerous researches. On these lines he endeavoured to obtain combination products uniting these two properties, which should be capable of causing, directly or indirectly, the death of the bacterium, of neutralising its toxins, and at the same time of being innocuous to the infected organism. Compounds were thus obtained with phenol and various lipoids, such as yolk of egg, cerebral substance, cholesterine, and lecithin, with camphor as the connecting link. These substances presented several common characteristics; they were nearly all semi-fluid in consistency and soluble in ether, benzol, chloroform, olive and essential oils. They were nearly all soluble in chloroform in proportion of 1 in 20, and when the solution was brought into contact with concentrated sulphuric acid gave rise to a green coloration passing into red. The particular substance, which presented a constant chemical composition, complete stability, and definite physico-chemical properties, was named by Dr. Piazza phenololipoid H, and was formed by the union of phenol with cholesterine and camphor. It is homogeneous, of pasty consistence, and whitish colour, melting at 70° C., solidifying at 15° C., and having a camphoraceous odour; it is insoluble in alcohol, acetone, glycerine, caustic alkalies, mineral acids, and water. Intravenous injections were toxic to guinea-pigs in doses of 1·5 cg. per 100 g. body weight, but subcutaneously it could be injected freely without disturbance even up to 15 cg. per 100 g. The antitoxic action of phenololipoid H was investigated on tetanus, diphtheria, and typhoid toxins, by bringing them into contact for varying periods of time and in special conditions. In the same way its action on emulsions of typhoid, dysenteric (Shiga), pneumococcal, streptococcal, and coli bacilli was tested. The results of these experiments proved that the phenololipoid H united in itself the parasitotropic action of phenol and the antitoxic action of cholesterine, the former being shown by the inhibition of bacterial development after a given period of contact, the latter by the neutralisation of the toxins of tetanus, typhoid, and diphtheria. It was, however, free from the organotropic action of phenol, having no local caustic or anæsthetic properties, nor had it any action on the red blood corpuscles or muscular fibres, and, in fact, realised the precise requirements of a chemotherapic agent, both antibacteric and antitoxic. Dr. Piazza's communication is in the nature of a preliminary note, and we await with interest further developments.

COMPLIMENTARY DINNER TO SIR JOHN MACALISTER.

THE complimentary dinner given to Sir John MacAlister by the Royal Society of Medicine on March 18th proved a very successful function from the only point of view that mattered—that is to say, that the acknowledgment of the profession of the services rendered by their guest to the cause of medicine was as sincere as it was imposing. Moreover, it was not to the recent knight that the compliment was being paid, but to the Secretary of the Society since 1887, through whose labours it was mainly brought about that the Royal Medical and Chirurgical Society had developed into the Royal Society of Medicine. The gathering at dinner was large and representative, and three of the speeches set out the history of the Society and its transformation, though all had "Our Guest" as their common theme. After a brief tribute from Sir Humphry Rolleston, chairman of the dinner, to MacAlister's qualities, Sir William Church spoke for the Berners-street period, and mentioned that their would have been no Hanover-square period had it not been for MacAlister's energy. Sir Rickman Godlee spoke for the Hanover-square period, and alluded to the skill of the secretary of the Society in husbanding the resources; and Sir Francis Champneys described the activities of the Society upon its arrival in its present home in Wimpole-street. To Sir Arbuthnot Lane fell the more genial task of introducing "the man" rather than his secretarial exploits to the company, but he also pointed out the great things pecuniarily that MacAlister had done for the Royal Society of Medicine. The health of Sir John MacAlister, with which was coupled the health of his wife, was then drunk with acclamation. In a quiet eloquent reply, Sir John MacAlister reviewed the parts played by the recent officers of the Society in erecting it into prosperity. The occasion was a notable one both for the quality of the gathering and the sincerity of the tributes paid to Sir John MacAlister as official and as friend.

EXPERIMENTAL TYPHOID.

ALTHOUGH the ætiological relationship of *B. typhosus* to typhoid fever has long been established beyond all reasonable doubt, the fact remains that the comparative failure to transfer the disease to animals has always required a more or less roundabout explanation. The habit of explaining things away has been described as "a running sore of the mind," and we are all the more pleased therefore that we are no longer compelled to indulge in this common, though repugnant, habit, in speaking of the typhoid bacillus and the fever to which it gives rise. Recent work[1] of Besredka has thrown a clear light on problems which have hitherto been wrapt in obscurity. Besredka's study of infection may be briefly summarised as follows. The rabbit has been found to be the most sensitive of the common laboratory animals to the typhoid bacillus and the poison it secretes. The effects produced depend upon the virulence of the organism and upon the route by which the organism is administered. Strains of *B. typhosus* which have been maintained for many generations in culture on artificial media are apt to lose some of their pathogenic power, and the results obtained by inoculation therefore vary considerably. With a very virulent strain injection directly into a vein may be followed by death within 24 hours. With ordinary laboratory cultures an illness of variable intensity is usually obtained. Post-mortem examination of animals thus treated shows that the bacilli are almost completely confined to the biliary tract and the upper reaches of the small intestine. Subcutaneous inoculation is less harmful than intravenous, and administration by the mouth is entirely innocuous. A rabbit may be fed with enormous numbers of typhoid bacilli, and beyond the production of agglutinins in the rabbit, no effects are noticed. Besredka has shown, however, that the simple expedient of giving a rabbit a few cubic centimetres of ox-bile some hours before feeding it with typhoid bacilli renders the animal sensitive. An acute illness follows in from one to four days, accompanied by diarrhœa, loss of weight, and profound prostration. The animal dies in from 3 to 15 days. The part played by the bile appears to be somewhat complicated. Acting as a cholagogue it stimulates the secretion of bile which flushes the small intestine clean. The excess of bile ruptures the integrity of the mucous membrane of the small intestine and thus provides the bacilli which are swallowed later with an opportunity of gaining an entrance into the blood stream. Further, the presence of bile in quantity no doubt assists the rapid multiplication of the invading bacilli.

THE MEDICAL SCHOOLS OF SOUTH AFRICA.

THE publication in the *Medical Journal of South Africa* of the plans for the Medical School in Johannesburg, now under construction, recalls a curious omission. The Medical Act of 1886, Part II., contains regulations for the inclusion in the Medical Register of the names of certain colonial and foreign practitioners holding diplomas recognised by the General Medical Council. The power of defining the countries to which this part of the Act shall apply belongs to the King in Council, and a fresh Order in Council is necessary before the Act shall be deemed applicable to any country other than those named in the tables appended thereto. The foreign lands at present scheduled are Italy, Japan, and Belgium—reciprocal facilities being given—and the British possessions are Australia, Canada, Ceylon, Hong-Kong, India, Malta, Newfoundland, New Zealand, and the Straits Settlements. The absence of South Africa from such a representative list has caused comment in the past in view of the large University at Capetown. Now that the attached medical school and a new school at Johannesburg are being organised, equipped, and staffed on modern lines to supply the whole course of medical studies, application is doubtless being made in the proper quarter for an Order in Council as a preliminary step to the recognition by the General Medical Council of the degrees conferred. Another anomaly that calls for adjustment on somewhat parallel lines is the refusal of the University of London, unlike Edinburgh and Dutch universities, to recognise the Cape matriculation as exempting from the London matriculation. This is one of the minor grievances of the native born and educated South African, and resented so keenly that by way of reprisal the South African School of Mines and Technology (University of South Africa) has hitherto denied admission for the diploma course to students who have only matriculated in England. The attitude of the University of London is doubtless based on the lower standard required for the Cape matriculation, but this difficulty would appear capable of solution by negotiations for a levelling-up of the standard or by recognition of passes in the first class only. In the present state of unrest in South Africa—evident from the recent elections—the desirability of avoiding any unnecessary sense of irritation with the home country and of forging further links of unity cannot be overstated.

THE ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND.

A PROVISIONAL programme has now been drawn up for the first annual meeting of this association, which will take place in London in May under the presidency of Sir John Bland-Sutton. An address will be delivered on the first evening, Thursday, May 13th, by the President. On Friday a discussion will be held at the Royal College of Surgeons of England in the morning on the Ritual of the Surgical Operation. The afternoons of Friday and Saturday will be employed in seeing operations and selected cases at the various London hospitals. On Saturday morning at the College there will be three short addresses: by Professor Arthur Keith on the History of the War Collection; by Sir George Makins on Selected Specimens of Wounds of Vessels; and by Sir Cuthbert Wallace on Gunshot Injuries of the Abdomen. The specimens in the war museum of the Royal College of Surgeons will be on exhibition.

THE Middlesex Hospital desire it to be known that the course of instruction for the D.P.H. advertised in THE LANCET of last week, p. 41, with the heading "University of London," should have been headed "The Middlesex Hospital Medical School (University of London)."

AN Order in Council, dated March 11th, sets up the Medical Research Council, to incorporate by charter the present members of the Medical Research Committee. Section 3 of the Ministry of Health Act, 1919, enacted that the duties heretofore performed by the Committee should, after the date of the commencement of the Act—namely, April 1st, 1920—be carried on under the direction of a special committee of the Privy Council. The Lord President of the Council, the Minister of Health, the Secretary for Scotland, and the Chief Secretary for Ireland, for the time being, constitute this special committee, the Minister of Health to preside in the absence of the Lord President, and the secretary of the Medical Research Council to act as its secretary.

[1] Bull. de l'Inst. Pasteur, xviii., No. 4, Feb. 29th, 1920, p. 121.

SIR ROBERT MORANT:

AN APPRECIATION BY DR. ADDISON.

Sir Robert Morant was more than a great public servant. He was a great patriot, a man of tireless self-sacrifice and deep enthusiasm. He was perhaps better known than many leading civil servants, but, in common with them, the full variety and the greatness of his work could only be fully known to those who worked with him.

My first close personal association with him was during the fierce political controversies which arose over the introduction of the National Health Insurance Act. He grasped at once the immensity of the task and the character and the extent of the organisation necessary to cope with the enormous mass of detail involved. Often in the struggle against time, as the day drew near for bringing the different services into operation, he would say, in his nervous, masterly way, that this or that could not be done. Yet it was done. It was done, because a man was in charge who had an indomitable spirit, an infectious energy, and a singular capacity for gathering around him a team of younger men whose standard was efficiency. He tolerated no inefficiency and was impatient of failure to act according to principles laid down. At the same time he was peculiarly sympathetic, often tender, to lowly members of his staff, and I have never known him fail to spare others rather than spare himself. Had his consuming conscientious energy been less active, he might perhaps be with us still.

Many a time in those days we tried to forecast the order of development and the nature of a system of organised health services which the nation so sorely needed. None was more conscious than he was of the difficulties in the way and of the time that would be required in overcoming them. Yet he was not dismayed when he realised that it would be necessary to deal with a medley of interests and authorities, an antiquated and cumbrous system of the Poor-law, a lack of trained personnel in all directions, a mass of vehement, deep-rooted prejudices, and, above all, with the common habit of thought that national health services were solely associated with physic and doctoring. He loved to talk of these things and longed to have a hand in the working. Often enough he would speak despairingly when he thought of the vicissitudes of political life, of the slowness of things, and of the lack and accidents of opportunity. When he fretted thus it was only because his eager spirit was anxious to be at work.

Among the many facts which the war made manifest was the urgent need of an organised system of health services, and I believe that he achieved one of the chief ambitions of his life on the day when it was my high privilege to ask him to become the first secretary of the first Ministry of Health. He saw before him an opportunity for years of useful work in the things he loved, and as a great practical idealist he rejoiced in the prospect. He never got lost in the thicket of details, of arrangements, rearrangements, adjustments, conferences, discussions, delays, and difficulties which attend the development of a progressive policy. All the time he knew where he was going, and his smallest actions were purposeful and designed to help things forward. He had the priceless gift of a wide view whilst retaining command over near and detailed work.

The tragedy of his loss would appal us all were it not for the unforgettable example of his dauntless courage. Those who really knew him loved him even for his foibles. There was nothing petty about him. When a course of action had been decided upon, he pursued it; the doubts and questionings that had preceded its decision having been carefully examined and estimated were cast behind him; whether he agreed in all respects or not he went straight on when the course was decided, and that annoying habit of lesser men of bringing up again and again all sorts of pointless questionings was never his. A great reasoner himself, he respected reasoning in others, and his masterful manner did not arise from any love of domination for its own sake, but from what he felt to be the necessities of the case. He was ready enough to subordinate himself and modify his views, and he looked for a similar practice in others. The cause was the only thing that mattered to him.

He was an inspirer of others, a magnificent chief of staff, greedy for labour in a worthy cause, a despiser of trifles and an affectionate and loyal friend, a tower of strength to whatever he supported, a devoted and splendid citizen. We are made poorer as a people by his loss. We are shocked by the tragedy of his death at the moment when he seemed to have the fullness of his power and opportunity. In our sorrow we can but reverence his memory and pay the tribute that he would value most in striving with all our might to imitate his great example. C. ADDISON.

THE PHYSICAL CENSUS.

I.

BEFORE detailing the outstanding results of the physical census conducted in 1917–18 and recorded in the Report of the Ministry of National Service, it is necessary to indicate the notation employed. All doubtless are familiar with the categories of the Army Medical Board.

> "A," men physically fit for active service at the front.
>
> "B," men able to undergo a considerable degree of physical exertion and with fair hearing and vision, but in consequence of partial disabilities unable to stand severe strain; fit for any form of service overseas but not for active service at the front.
>
> "C," men who in consequence of physical disabilities cannot undertake marching but can be employed for less arduous and more sedentary occupations.
>
> "D," the rejected, unfit for any form of military service.

We owe to Professor Arthur Keith the translation of these categories into Groups I. to IV., which is a more scientific subdivision of the material in the terms of the polygon of frequency. Professor Keith worked on the assumption that physical fitness—the quality which separates men into grades—would be distributed amongst recruits exactly as are certain qualities capable of exact measurement, such as stature. Of a thousand Cambridge students measured for stature, those measuring 5 ft. 9 in. formed the largest group. Those measuring more and less than this tailed off inch by inch on either side of this mean with striking symmetry. Applying this method to general physical efficiency, he lays down that in a normal population measured for height, weight, and chest girth 70 per cent. should be included in Grade I., which is constituted of the mean or largest class, and also comprises all above the mean and the class just below the mean; 20 per cent. should constitute Grade II. (corresponding to the "B" men); 7·5 per cent. Grade III. (the "C" men); and 2·5 per cent. Grade IV. men, or rejects. Thus, from a military point of view, each 1000 men of the adult population should provide—

700 (seven companies) of Grade I.
200 (two companies) of Grade II.
75 (seven and a half platoons) of Grade III.
25 (two and a half platoons) of Grade IV.

This we may speak of as Keith's "index of efficiency." Giving each man of Grade I. the value = 1, and the men of the other grades a value equal to 0·75, 0·5, and 0·25 respectively, the total value of 1000 men of the normal population should sum up to 893·75 units of fitness. He therefore speaks of 89·3 as "the index of fitness."

The main results received may be thus reviewed:

1. During the year 2,425,164 men presented themselves for examination and re-examination (these latter comparatively few in number, so that they do not materially influence the results).

2. Instead of there being found 700 Grade I. men per 1000 there were found only 359; instead of 75 Grade III. men there were 312 ("C" men) and 104

Grade IV. men in place of a normal 25. Or taking the actual number of examinations during the year:—

—	I.	II.	III.	IV.
Actual number placed in each grade	871,769	546,276	*756,859*	*250,280*
Number anticipated from normal population by Keith's standard	*1,697,595*	485,040	181,902	60,647
—	– 825,826	+ 61,236	+ 574,957	+ 189,633

Or, roughly, out of 2½ million men there was a shortage of 825,000 men fit for active service, and the alarming excess of no less than 575,000, or more than half a million C men and 190,000 D men.

3. The incidence of this deficiency of Grade I. men and excess of Grade III. men varied greatly in the different regions, and particularly in the different regions when account was taken of the predominant occupations. The London and South-East district yielded only 28·2 per cent. A men (in place of 70), Scotland yielded 44·2, and Wales 46 per cent. The best returns came from Wales, the worst from London and the South-East region. There was a difference of almost 10 per cent. in the index of fitness of these two regions.

Certain localised districts gave figures well above Keith's standard. The subjoined table, giving the results of the medical examination of different groups of men aged between 18 and 25 in Yorkshire, indicates very significantly the direct relation which exists between occupations and physical condition:—

Occupation.	% Grade I.	% Grade III.
Agriculturists (1st group)	74·8	9·4
Miners (,,) ...	76·4	11·4
Keith's standard	70·0	7·5
Agriculturists (2nd group)	71·9	8·8
Miners (,,)	68·9	10·5
Agriculturists	62·0	11·6
Engineers	60·9	13·4
Iron and steel workers	60·2	11·2
Lace workers	45·0	22·7
Woollen trade	54·6	24·0
Woollen trade (2nd group)... ...	37·5	27·0
Tailors	33·9	33·5

It will be observed that (coal) miners and agriculturists show far and away the best grading results, and that among them Keith's standard may be exceeded. Mining and agriculture are both industries which were highly protected against recruitment, and the men who were ultimately combed out in 1918 may be regarded as typical of their class from a physical standpoint. At the other extremity of the scale come the workers in cotton and woollen mills; 290 cotton operators examined by the Stockport board in April, 1918, yielded only 19·6 per cent. of Grade I. men, and had an index of fitness of 57·9 in place of 83·9. In the same month 5001 men examined at Leeds gave 40·5 per cent. Grade I. men, and 31·1 per cent. Grade III., while 8919 men at Sheffield gave 66 and 13·6 per cent. respectively. Or taking the combined results of January, April, and June, out of 1000 men, Sheffield yielded a battalion made up of six companies, Leeds one made up of only 2·85 companies. Even Sheffield is a company short of the normal. It is difficult to arrive at any other conclusion than that either the woollen industries of Leeds attract men of painfully low physique, or that the result of working, under the conditions present in the woollen mills, is to bring about a rapid, not to say appalling, deterioration in the physical condition of the operatives. The Commissioner of the region attributes these results in Leeds to the following factors: (*a*) the large number of back-to-back houses; (*b*) the very large alien population engaged in tailoring at home under very bad sanitary conditions; (*c*) the large number of women employed in clothing and other factories, this circumstance tending to favour the incidence of rickets in their children with lowered physical condition later in life; and (*d*) the frequency of infantile paralysis. The industrial population of Sheffield is almost entirely employed in the iron and steel industries, work requiring men of good physique, and there female labour is at a minimum.

The qualities of the information afforded by the report in these directions are thus indicated; full returns are promised with tables for the whole country. But the value of the figures, and the weight that may safely be given to them, can be estimated, as will be shown.

MEDICINE AND THE LAW.

The Law Relating to Coroners.

THE Home Office is engaged in working out the details of the long-promised Bill to amend the law relating to coroners and the holding of inquests. It is more than 30 years since the last important Act amending and consolidating the law relating to coroners was passed. Ten years ago the committee presided over by Sir Mackenzie Chalmers expressed in its report its astonishment at "the good work done by coroners with out-of-date and imperfect machinery." The committee went on to make many suggestions for improving the provisions of the Act of 1887, most of which await the consideration of the Legislature. It recommended the prescribing of a professional qualification for coroners, the majority of whom at that time were found to be solicitors, some barristers, and a good many medical men. Others, however, had no professional qualifications. It dealt with remuneration and expressed itself in favour of fixed salaries and as adverse to the income of the coroner being dependent upon the number of inquests held by him. It dealt also with the desirability of an age-limit, and of pensions on retirement, and recommended that the coroner should be ex officio a justice of the peace. The authority to order a post-mortem examination, otherwise than as part of an inquest, was one of the most important powers that the committee advised should be given to coroners, and one with which coroners, and especially medical coroners, had long asked to be invested.

The committee also was of the opinion that for the procedure of the coroners' court a rule-making authority should be constituted to replace the limited powers of the Lord Chancellor to prescribe forms under section 18 of the Coroners Act, 1887. Some of its recommendations affected the making up of jury lists and other questions relating to juries. No doubt the present power to dispense with juries, due to the exigencies of war, will have afforded useful experience, by which those responsible for the coming Bill will have profited. The viewing of the body will be another point which presumably will have received consideration. The question of the selection of medical witnesses, and that of their remuneration, will require adjustment in terms of the present cost of living. The recommendations of the committee will, no doubt, be carefully weighed. Ten years constitute a long interval between the obtaining of advice in a matter of public interest and the carrying of it into effect.

The Detention as Lunatics of Ex-Service Men.

A question was asked recently by Colonel Wedgwood in the House of Commons as to how many persons are being detained in public or private lunatic asylums, and as to the number of these who are ex-Service men, voluntary boarders, or temporarily detained respectively. The answer given by the Under Secretary for Home Affairs, replying for the Minister of Health, referred to England and Wales, the total number of patients given being 96,344 (males 42,294, females 4050), of whom 3739 are ex-Service men classified as such and a few are ex-Service men not so sanctioned by the Ministry of Pensions or whose sanction is pending. The voluntary boarders in private asylums are 270 (males 108, females 162), none being temporarily detained. From these figures no inference can, of course, legitimately be drawn as to whether any increase of insanity or degeneracy has taken place recently. Progress in the study of mental unsoundness is likely to lead to an increase in the number of persons treated in institutions. There are, however, obviously no statistics available as to the number of persons to whom such treatment might be beneficial, and Sir H. Brittain's question whether "we have any statistics showing how many persons are at large who ought to be in asylums" remains unanswerable. The honourable Member might have had difficulty in assigning a meaning to the word "ought" in such a connexion. On the same occasion Lieutenant-Commander Kenworthy asked whether it would be possible to concentrate the ex-Service men in one or two establishments and give them special treatment. Major Baird intimated that he would not reply to this question without notice. An answer might, however, have been given that such a course would be possible if any advantage could be proved to be obtainable by such a course sufficient to render it worth while. Special institutions for ex-Service men might or might not be more agreeable to them and to their relatives. Those mentally unable to realise their surroundings would not be affected, while the convalescent might prefer to be nearer their homes. Relatives of both classes would wish to visit them without having to travel to a distance in order to do so. There would then remain the further question whether men suffering from similar causes connected with their hardships and experiences in the war would benefit by being congregated together. That is a question with a quite important medical side.

Medical Grounds for Refusal to Marry.

Mr. Justice Darling, sitting without a jury, recently awarded one farthing as damages in an action for breach of promise of marriage, and refused to order the payment of costs by the defendant. The case was of interest owing to the defendant admitting a promise to marry made before 1914, and at the same time denying the allegation of the plaintiff that he had made a promise in August, 1918, to marry her, and pleading that owing to injuries received in France he had become physically and mentally unfit for marriage and its obligations. This he had realised in the autumn of 1918, when he had informed the plaintiff of his condition. Medical evidence was given in support of his decision, and was to the effect that at that time marriage, and even the excitement of the ceremony, would have been injurious to him. Mr. Justice Darling, after reviewing the evidence, expressed the opinion that in the interests of both parties the conclusion arrived at by the defendant was a very reasonable one. Many might regard marriage as a mere trifle, and bigamy as only a little more serious, but, in his lordship's view, marriage, still nominally a contract for the life of both parties, was a very serious undertaking. This it would remain, however the law might be altered, for the reason that it generally resulted in the birth of children. The marriage under discussion might have resulted in the birth of children who would have been a burden to the State. This was to be gathered from the medical evidence, and if the plaintiff had married the defendant her life might have been one of misery. His lordship expressed himself in accord with the views propounded by Lord Bramwell in a dissentient judgment in the Court of Exchequer Chamber, in the case of Hall *v.* Wright (El. & E. 746). Lord Bramwell there said that it was implied in the marriage contract that the man or woman should be able to carry it out without danger to life and without danger of producing idiots or children of that type. The Court of Exchequer Chamber declined to adopt that view, and held that such a term was not implied in the marriage contract, but Mr. Justice Darling believed Lord Bramwell to be right. He would be prepared to say that the defendant was right in refusing to marry the plaintiff provided that he was in such a state that marriage would be dangerous to him and disastrous to the State by the begetting of idiot children. His lordship was, however, unable to say that the medical evidence went to the full extent of the proof needed, and in that it failed in this the contract had been broken without legal excuse and the defendant's plea was not established. Judgment, therefore, must be for the plaintiff.

Proceeding to assess the damages, Mr. Justice Darling considered that however much the plaintiff's feelings might have suffered, if she were a reasonable woman she would say that she had escaped very great danger of a miserable life. Further, it appeared that she had not lost a rich husband or a man of high position. The defendant was now in receipt of £40 per annum as a kind of compassionate allowance, for doing light work in an institution for wounded soldiers, and the plaintiff had lost nothing of any value. He therefore assessed the damages at a farthing, and refused to make an order that the defendant should pay costs, expressing the opinion that it was not to the plaintiff's advantage or to the public interest that such an action should have been brought.

It will be seen that the importance of Mr. Justice Darling's judgment lies in his reliance on, and revival of, the statement of Lord Bramwell's opinion. Lord Bramwell was a sound lawyer and a man of vigorous mind and strong "common-sense." In this instance he seems to have anticipated the scientific point of view of a generation later than his own. When a verdict has been found for a defendant based upon Lord Bramwell's judgment in Hall *v.* Wright an opportunity will no doubt be given for review of this important legal and social question by the Court of Appeal.

CONTROL OF VENEREAL DISEASE.

The Attitude of Women towards Preventive Measures.

Two recent meetings of women are interesting in showing an increasing readiness to accept the position that advocacy of early disinfection is not incompatible with the dictates of morality when the measures suggested are enunciated in the right spirit. At the Portsmouth branch of the N.C.C.V.D. on March 8th Miss Norah March addressed women on "Propaganda for Prevention of Venereal Diseases." Mrs. K. Edmonds, the honorary secretary of the branch, who occupied the chair, stated that the day was coming when the teaching and practice of prevention would take a normal place in the campaign against venereal diseases. This meeting was largely attended by women representatives of various societies and their friends. At the seventh annual meeting of the Leicester and Leicestershire Midwives Association, held two days later, Mr. C. J. Bond in the chair, the following resolution was passed:—

> That though this association approves of immediate treatment and, where practicable, of self-disinfection after exposure to the risk of venereal infection, it does not approve of the distribution to the public of prophylactic packets, and it feels very strongly that any instruction written, printed, or otherwise given on the subject should include a carefully worded statement pointing out the immorality of promiscuous sexual intercourse, as well as the danger thereby incurred of venereal disease.

Mrs. James Bilson, who seconded the resolution, set out clearly the arguments for early self-disinfection, and no dissentient voice was heard. After discussion the resolution was carried unanimously. Mr. Bond laid stress upon the necessity for midwives to realise their great opportunities for helping in the anti-venereal campaign. He regarded the present marked lowering of the moral standard as the chief factor in the spread of venereal diseases.

Portsmouth's Experiment in Prophylaxis.

By a resolution recently passed,[1] the Health and Housing Committee of the Portsmouth Borough Council adopted a report by its medical officer of health, Dr. A. Mearns Fraser, and urged its council to empower them to take the steps recommended by him with a view to the prevention of venereal disease. Dr. Fraser in his report laid stress upon the prevention of disease rather than its treatment as the more appropriate function and aim of a health authority, and explained the nature of the measures for self-disinfection most likely to be carried out by the ordinary man indulging in promiscuous sexual intercourse. With regard to the part to be taken by the council as sanitary authority in promoting such self-disinfection, he did not advocate the provision by it of "packets" or of the preparations which would be used in them, but that it should take such steps as might be necessary to spread a knowledge of the means of self-disinfection. He also pointed out that in the endeavour to check the spreading of venereal disease by advice as to disinfection there was nothing inimical to, or incompatible with, the prosecution of other measures at the same time for the promotion of chastity. It will be interesting to know later the means adopted at Portsmouth for the dissemination of the precautionary knowledge suggested and the results so far as they are traceable. These should to some extent be ascertainable by the collection of information as to the sale of the disinfectants recommended, and as to the comparative number of cases treated, wherever trustworthy figures can be obtained. This assumes, of course, that the Portsmouth Borough Council adopts the recommendation of its Committee and follows it with energy. The simultaneous carrying out of similar measures in other districts would, in time, enable a correct judgment to be formed as to the value of instruction of the kind indicated when distributed by public authorities. In such cases those also who fear that immorality may be increased by public measures for its prevention will have an opportunity for verifying their predictions or for seeing them unfulfilled.

[1] THE LANCET, March 13th, p. 634.

Association of Officers at Treatment Centres.

Practitioners in charge of or working at V.D. clinics realise the advantage which would accrue from the discussion of clinical and other subjects immediately connected with their work. In small towns it must be difficult for them to achieve this end, but in the larger ones the medical officers of clinics might well arrange to meet, say once a month, for the purpose of discussing certain aspects of their work which had been previously selected. And the discussions might be accompanied by the exhibition of illustrative cases. By means of such an organisation useful research work would be inaugurated. As an example, we would cite the desirability of comparing and contrasting the value of various methods of treatment. Friendly coöperation on these lines would allow of one method being put into effect at one clinic whilst other methods were practised elsewhere. Another gain from such association might be the formation of a library dealing with venereal diseases in all their aspects, including both text-books, monographs, and the periodic literature, which in the majority of cases it would be impossible for the individual officer to obtain. From time to time a well-known venereologist might be invited to address the members on some subject of common interest. Such associations would not only make for the increased dignity of this branch of medicine, but should foster a spirit of comradeship and a friendly competition amongst its members.

The Study of Venereal Diseases at Strasbourg University.

A practical course of instruction for practitioners and foreign medical men in venereal diseases is to be held by Professor L. M. Pautrier and his assistants at the dermatological clinic of the Faculty of Medicine of Strasbourg University from May 1st till July 14th. The course will comprise 40 classes at the clinic and 10 classes on laboratory technique, and its scope will be entirely practical. Every student will have the opportunity of actual manipulative treatment of patients, including the administration of intravenous injections, and will receive a series of microscopic slides, also a certificate of attendance. The library of the University and the local hospitals will be open to students, who are asked to apply to M. le Professeur Pautrier, Clinique des maladies cutanées de la Faculté de Médecine, Hôpital civil, Strasbourg, for further particulars. The fee for the whole course is 300 francs.

TUBERCULOSIS.

New Lights on the Epidemiology of Phthisis.

SINCE the establishment of the relation of Koch's bacillus to tuberculosis there has been a deplorable tendency to regard the main problem in connexion with this disease as solved. Let the principles governing the control of other infectious diseases be logically applied to Koch's discovery, and this disease, too, it is assumed, will vanish as surely as night follows day. Segregation, tuberculin therapy, and a host of other measures are advocated as the obvious remedies for a well-defined disease which fits neatly into the niche provided by that much-abused term, a nosological unit. A useful corrective to this complacent attitude is to be found in Dr. J. Brownlee's "An Investigation into the Epidemiology of Phthisis in Great Britain and Ireland," Part III.[1] Though his study is statistical, he treats his subject, on the whole, in a suggestive rather than in a dogmatic manner. And wherever he is dogmatic, he also shows a catholic appreciation of the complexity of the problems with which he is concerned. At least one definite and logical conclusion emerges from the mass of evidence available. Tubercle among young adults on the one hand, and middle-aged persons on the other, shows so many and such fundamental differences that it cannot be regarded as one and the same disease. No valid interpretation of the decline of phthisis during recent years can be simple; it must pay regard to the multiple nature of the types of the disease. In an earlier report Dr. Brownlee distinguished between the phthisis of young adult life and that of middle age. He also identified an old-age type closely related to that of young adult life. These two, or possibly three, types of disease correspond with separate types of bacillus, or, as Dr. Brownlee is less inclined to believe, they mark different types of response made by the human body to the infection at different ages. The present report gives further evidence establishing the validity of this differentiation into types. It shows that, while the young-adult and old-age types of phthisis vary almost independently of the hygienic surroundings, the middle-age type is very closely correlated with the general standard of health as measured by the death-rate. The young-adult type of the disease, unlike that of middle-age, seems to be more common where the feeding is poor and where little attention is paid to wet and damp. In some regions, at least, it can be correlated with exposure to south-west winds and to characters of the soil. Dr. Brownlee's investigations show that the young-adult type is more common above glacial clay than glacial sand or the highly organic London clay. It is less common in districts with a comparatively high death-rate from tuberculosis in childhood and in districts in which there is much middle-age phthisis. It is also less common in counties from which a large amount of tubercle-infected milk is sent to London. On the other hand, it appears to bear no relation to hygienic surroundings nor to the disease of the population. Indeed, it would seem to be a disease rather of the country than of the town, and one bearing no relation to the density of the population.

Very different are the characteristics of phthisis at middle age. It appears to be independent of wind, and in London, for instance, its incidence is as great in such exposed parts as Hampstead as in the sheltered valley of the Thames. It appears also to be independent of the nature of the subsoil. On the other hand, it is comparatively common in districts with a high death-rate from tuberculosis in childhood and with a large amount of tuberculous milk. It is intimately related to the general hygiene, as measured by the death-rate, and to the density of the population. As for the phthisis of old age, it does not appear to be related to subsoil, hygienic conditions, density of population, or any other direct external factor. The only association definitely established is with the employments of coal. iron, and lead mining and slate-quarrying. But the cause of this association is at present quite unknown.

---

[1] Medical Research Committee, Special Report Series, No. 46, H.M. Stationery Office, pp. 89.

The value of Dr. Brownlee's work is not confined to the material he has collected and analysed, important as this is. He has submitted working hypotheses by which a mass of other available but hitherto imperfect knowledge may be criticised and assessed. Possibly his hypotheses may solve some, at any rate, of the many problems of tuberculosis that have hitherto been shelved as incomprehensible paradoxes. To the single-minded, who see in phthisis nothing but a paraphrase of the housing problem, it is discomforting that in Christiania the death-rate from tuberculosis has steadily declined during the war in spite of (and who is bold enough to suggest because of?) an unprecedented shortage of houses and consequent overcrowding. Yet in the northern, thinly populated districts of Norway tuberculosis is increasing at such an ominous rate that decimation, if not extermination, is threatened. And how can we interpret, with the knowledge hitherto at our disposal, the observations made many years ago by Professor Johannessen, who found that, at a training college in the east of Norway where the disease is prevalent, the death-rate from pulmonary tuberculosis was ten times as great among pupils from the west coast, where the disease is comparatively rare, as it was among the pupils drawn from the neighbourhood of the college? Frankly we cannot. But light may be thrown on these and countless other observations if illumined by Dr. Brownlee's hypotheses. In the sphere of research his is a challenge to bacteriologist and clinician alike. To the advocates of hasty administrative action, panting to dragoon consumption out of existence by the expenditure of millions on the policing of consumptives, he offers a sobering draught of agnosticism.

Though he covers a wide field and opens up many new paths to future progress, Dr. Brownlee presents his main thesis in a crisp and concise form—a remarkable achievement considering the figures with which he juggles. His candid confession of the limitations of the statistician's sphere of usefulness will, no doubt, go some way towards disarming critics constitutionally disposed to regard statistics as mendacity systematised. Thus far, and no farther, is Dr. Brownlee's own verdict on his findings. "The matter for the moment must be left in this state until it has been seriously tackled by the bacteriologists. Statistics alone will not give the solution."

Factors in the Increase of Consumption.

Many explanations have been given of the increase of pulmonary tuberculosis in recent years, and doubtless it is due to several causes. Two clear facts must be kept in mind when weighing the respective importance of different factors—viz., that the rise began before the war and has been concurrent with the rise and fall of influenza. The increase since the war is in great part apparent only, and due to elimination from the country of a large section of the most healthy class of the population. The February number of the *Journal of State Medicine* contains two articles on the early diagnosis and treatment of this disease. Dr. Halliday Sutherland thinks it is more reasonable to attribute the higher death-rate from both tuberculosis and influenza to lowered resistance due to vitamine starvation during the war rather than to failure of existing methods of prevention. A more ample supply of butter and fat meat is much to be desired. But whatever the source of the recrudescence of tubercle bacilli, it is of supreme importance that the mischief they are working should be detected at the earliest possible moment, and to this end Dr. Sutherland's reasoned appeal to the general practitioner not to postpone his diagnosis until tubercle bacilli is found in the sputum should be taken to heart by all who wish to cure their patients and bear their part in the fight against tuberculosis. Tubercle bacilli in the sputum indicate that the lung is breaking down and the disease already advanced. Dr. Sutherland insists on the value of loss of appetite and dyspepsia as early symptoms, calling for the application of such special tests as X rays and tuberculin. Dr. Hyslop Thomson moots the suggestion that not only bovine tuberculosis is produced by milk, but also human by transmutation from bovine through prolonged residence in the human host. The possible truth of such a theory gives additional reason to call for immediate application of the "Tuberculosis Order, 1913," and the "Milk and Dairies (Consolidation) Act, 1915," which have been waiting till the completion of the war.

A Well-authenticated Epidemic of Tuberculosis.

The medical supplement to the forty-eighth (and last) annual report of the Local Government Board, to which we have already referred on several occasions, contains a very interesting account by Dr. A. S. MacNalty of an outbreak of severe illness in a home authorised to receive girls from boards of guardians. Forty cases of illness occurred with eleven deaths. The possibilities of certain of the cases being croupous pneumonia and of the existence of a concomitant outbreak of influenza were considered and excluded. Tuberculosis was of long-standing in the institution, a focus of tuberculous infection existing as far back as 1913, while a fatal case of pulmonary tuberculosis occurred in 1915. The infection was probably introduced from without. The girls came from bad surroundings, exposed to tuberculous infection in infancy. Some had a pronounced family history of tuberculosis, and many entered the home at the 12–15 age-period, when their physical efficiency was already impaired. Unsatisfactory conditions in the home favoured the spread of tuberculosis by contact infection. The administration of the home was defective: the beds were overcrowded; there was no trained nurse on the staff; complaints of illness by the girls were discouraged; the dietary was meagre; there was lack of regular exercise and interference with the hours of sleep. Dr. MacNalty thinks that tuberculous infection had been accumulating for a number of years, passage from individual to individual gradually exalting its virulence until an explosive outbreak occurred. His report indicates that, given a community of persons with some predisposition to tuberculosis, the introduction of tuberculosis into this community, the infection being favoured by unsatisfactory conditions of environment, may result in an epidemic of a rapidly fatal character. The report, which appears in abstract only, deserves to be printed in full and to have the widest publicity.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Scottish Board of Health: Consultative Councils.

ON Friday, March 12th, the members of the four Consultative Councils established by the Scottish Board of Health were addressed in Edinburgh by Mr. Munro, K.C., M.P., Secretary for Scotland. Mr. Munro said that the Consultative Councils had been appointed to arrange and advise regarding four separate matters—medical and allied services, National Health Insurance, local health administration and general health questions, and the special problems of the Highlands and Islands. He desired to welcome them on behalf of the Board of Health and himself, and to have the opportunity of emphasising the common purpose for which these bodies were alike designed and fitted to serve. It was the intention of the Board that all the bodies should have the fullest opportunity of forming and expressing free and independent judgments on the questions on which they had to deliberate; they would select their own chairmen and regulate their own procedure. For the effective working of the Councils it was essential that there should be the very frankest interchange of confidence between them and the Department, and a ready interchange of views and opinions between the members themselves. The Board would place at its disposal all the information in their possession which they might reasonably require in arriving at decisions. As a counterpart the Board would expect them to respect its confidence, and observe proper discretion with regard to the information which would be placed at their disposal. The duty of the Board, as expressed in the Act of Parliament, was "to secure the effective carrying out and coördination of measures conducive to the health of the people." That was its watchword and charter, and the members of the Councils were invited to coöperate to achieve that supreme and inspiring purpose. The questions which had been referred to the Councils bore intimately upon that master purpose, among these being "the question of a reformed local authority for health administration, its area and constitution, and the powers and duties to be transferred to it"; "the question of applying to Scotland the principles of the Maclean Committee's report on the transfer of functions of Poor-law authorities in England and Wales." It had also been referred to them to consider the provision of such forms of medical service as they considered should be available for the community, the question of medical research in Scotland, and to consider whether the present hospital service is adequate and to make recommendations for its improvement or for the provision and maintenance of an adequate service. These were examples of the great problems which had to be solved and which would require all their skill and experience. The establishment of the Board of Health was intended to prepare the way for a vigorous campaign to raise the standard of health of the people of this country. There was no nobler object, and for its attainment it required the full support of public opinion, and hearty coöperation between the Department and the Councils on the one hand, and the interests affected on the other hand. It would be the special function of the Councils to ensure success along these two lines, and to keep in close touch with opinion outside. He was certain they could undertake a profoundly important share in making the country a healthier, and therefore a happier, place, and in assisting Scotland to lead the way in this vital national enterprise.

Notification of Acute Encephalitis Lethargica.

A memorandum has been issued by the Scottish Board of Health explaining the nature and symptoms of acute encephalitis lethargica. The disease has so far been of rare occurrence in Scotland, and the Board suggest to medical officers of health that they should circularise all the medical practitioners within their districts if the nature of the area and the circumstances indicate its advisability. After summarising the clinical features of the disease, the memorandum proceeds:—

> Acute encephalitis lethargica, though it has occurred in England in epidemic form, has never attained to extensive proportions. But it is important that in all parts of Great Britain an informed outlook should be kept for its recurrence. Little is known regarding its essential nature, the channels by which it is spread, or, consequently, the means by which it may be prevented and controlled. That lack of knowledge, along with its high case-mortality and its resistance to treatment, make it important that every case should be recognised and studied. It is therefore desirable that cases suspected to be of the nature of acute encephalitis lethargica or even considered remotely to resemble it should be intimated to the medical officer of health, who should afford every facility towards confirmatory diagnosis, treatment, and such isolation as he considers necessary. With this end in view it is desirable also to bring to his notice cases of ordinary acute poliomyelitis.

The memorandum is based upon the report to the Local Government Board (England) of an Inquiry into an Obscure Disease, Encephalitis Lethargica (1918; H.M. Stationery Office; 2*s.* 6*d.*).

BRISTOL HOSPITALS: ANONYMOUS CONDITIONAL GIFT.—The Lord Mayor of Bristol recently stated that £100,000 had been anonymously offered to the funds of the hospitals of Bristol provided they undertook an amalgamation along the lines now under consideration. An interesting feature of the plan for amalgamation (so far as it has been made public) is the provision for representation of the University on the council to which it is proposed to entrust the control of the hospitals.

URBAN VITAL STATISTICS.

(Week ended March 20th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had increased from 15·6 to 17·1 in the four preceding weeks, further rose to 17·9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 17·8, or 0·6 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 9·0 in Oxford and in Warrington, 9·3 in Acton, and 9·8 in Wallasey, to 27·2 in Barnsley, 29·9 in South Shields, and 49·2 in Dudley. The principal epidemic diseases caused 504 deaths, which corresponded to an annual rate of 1·5 per 1000, and comprised 230 from measles, 120 from whooping-cough, 69 from diphtheria, 57 from infantile diarrhœa, 24 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 3·0 in Nottingham and Newport (Mon.), 3·2 in West Hartlepool, 3·6 in St. Helens, 4·0 in Barnsley, and 5·4 in Wigan; and whooping-cough of 2·1 in Barrow-in-Furness and 6·2 in Gloucester. The deaths from influenza, which had steadily increased from 66 to 230 in the seven preceding weeks, further rose to 312, and included 91 in London, 40 in Birmingham, 16 in West Ham, 13 in Leeds, 11 each in Manchester and South Shields, and 10 in Plymouth. There were 2158 cases of scarlet fever, 2066 of diphtheria, and 8 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2182, 2045, and 7 respectively at the end of the previous week. The causes of 48 deaths in the 96 towns were uncertified, of which 12 were registered in Birmingham, 5 in Liverpool, and 4 each in London and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had increased from 14·2 to 16·0 in the four preceding weeks, further rose to 17·8 per 1000. The 407 deaths in Glasgow corresponded to an annual rate of 19·1 per 1000, and included 11 from influenza, 9 from measles, 5 each from whooping-cough and infantile diarrhœa, 4 from diphtheria, and 2 each from enteric fever and scarlet fever. The 87 deaths in Edinburgh were equal to a rate of 13·3 per 1000, and included 2 from influenza and 1 each from measles and diphtheria.

Irish Towns.—The 195 deaths in Dublin were equal to an annual rate of 24·5, or 4·5 per 1000 above that recorded in the previous week, and included 9 from whooping-cough, 3 each from measles and infantile diarrhœa, 2 from influenza, and 1 each from enteric fever, scarlet fever, and diphtheria. The 293 deaths in Belfast were equal to a rate of 37·0 per 1000, and included 33 from influenza, 8 from whooping-cough, 6 from infantile diarrhœa, 5 from scarlet fever, 3 from measles, 2 from enteric fever, and 1 from diphtheria.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1920.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 7·7 per 1000 of the population, estimated at 4,358,309 persons; in the three preceding months the rates had been 10·5, 9·9, and 8·5 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Kensington, Hampstead, Islington, Finsbury, the City of London, and Bermondsey; and the highest in Fulham, Holborn, Bethnal Green, Wandsworth, Deptford, and Greenwich. The 3 cases of small-pox notified during the month belonged to Poplar. The prevalence of scarlet fever showed a slight decrease from that recorded in January; this disease was proportionally most prevalent in Stoke Newington, Stepney, Lambeth, Deptford, Greenwich, and Lewisham. The Metropolitan Asylums Hospitals contained 2266 scarlet fever patients at the end of the month, against 2848, 2841, and 2476 at the end of the three preceding months; the weekly admissions averaged 279, against 427, 350, and 280 in the three preceding months. Diphtheria was slightly less prevalent than in the preceding month; this disease was proportionally most prevalent in Paddington, Hammersmith, Fulham, Holborn, Bethnal Green, and Wandsworth. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1572, 1845, and 1971 at the end of the three preceding months, numbered 2003 at the end of February; the weekly admissions averaged 240, against 215, 239, and 263 in the three preceding months. The prevalence of enteric fever was about equal to that in

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING FEBRUARY, 1920.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1919.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total. * Including membranous croup.

the preceding month; of the 39 cases notified during the month 7 belonged to St. Marylebone, 6 to Hampstead, and 3 each to Hammersmith, Poplar, Wandsworth, and Greenwich. There were 30 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 44, 25, and 25 at the end of the three preceding months; the weekly admissions averaged 6, against 5, 2, and 4 in the three preceding months. Erysipelas was proportionally most prevalent in Stoke Newington, Holborn, Finsbury, Bethnal Green, Southwark, and Deptford. The 45 [illegible] of puerperal fever included 5 in Wandsworth, 4 in Islington, 4 in Camberwell, and 3 each in Fulham, Poplar, and Battersea. The 9 cases of cerebro-spinal meningitis included 2 in St. Pancras and 2 in Poplar; while the 2 cases of poliomyelitis belonged respectively to Hampstead and Islington.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended Feb. 28th, the deaths of 5564 London residents were registered, equal to an annual rate of 16·6 per 1000; in the three preceding months the rates had been 13·5, 13·1, and 14·6 per 1000. The death-rates ranged last month from 10·2 in Hampstead, 11·6 in Woolwich, 12·0 in the City of Westminster, 12·9 in St. Marylebone, 13·0 in Wandsworth, and 13·4 in Lewisham, to 20·1 in Stepney, 20·2 in Bethnal Green, 21·1 in Finsbury, 21·5 in Holborn, 22·5 in Southwark, and 25·2 in Shoreditch. The 5564 deaths from all causes included 504 which were referred to the principal infectious diseases; of these 1 resulted from small-pox, 162 from measles, 15 from scarlet fever, 96 from diphtheria, 157 from whooping-cough, 3 from enteric fever, and 70 from diarrhœa and enteritis among children under 2 years of age. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Chelsea, the City of Westminster, St. Marylebone, Hampstead, Finsbury, Wandsworth, and Woolwich; and the highest in St. Pancras, Hackney, Shoreditch, Bethnal Green, Bermondsey, and Greenwich. The fatal case of small-pox belonged to Poplar. The 162 deaths from measles were 27 in excess of the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in St. Pancras, Hackney, Holborn, Shoreditch, Bermondsey, and Greenwich. The 15 fatal [illegible] of scarlet fever were 4 fewer than the average, and included 2 in Paddington, 2 in St. Pancras, and 2 in Camberwell. The 96 deaths from diphtheria exceeded the average by 34; the greatest proportional mortality from this disease occurred in Paddington, Stoke Newington, Hackney, Bethnal Green, Southwark, and Greenwich. The 157 fatal cases of whooping-cough were 54 in excess of the average; this disease was proportionally most fatal in Kensington, Hackney, the City of London, Bethnal Green, Stepney, and Bermondsey. Three deaths from enteric fever were registered during the month, against an average of 6; these deaths belonged respectively to Hackney, Poplar, and Southwark. The 70 fatal cases of infantile diarrhœa were 6 above the average; the greatest proportional mortality from this disease occurred in Hammersmith, Holborn, Bethnal Green, Battersea, and Camberwell. In conclusion, it may be stated that the aggregate mortality in London during February from these principal infectious diseases was 30 per cent. above the average in the corresponding period of the five preceding years.

AN inquest was held recently at Lowestoft on a plumber employed by the G.E.R. It appeared that on Oct. 5th, 1918, while testing the pressure of the gas in a gas-main [illegible] one of the quays at Lowestoft he had inadvertently inhaled a quantity of gas. He went home, and was attended for a week by a doctor, who gave him a certificate, stating that he was suffering from hæmorrhage of the lungs caused by gas poisoning. From the time of the accident the man's health deteriorated, and he eventually died from pulmonary tuberculosis about 18 months after he was poisoned by the gas. Dr. L. H. Hay, who gave medical evidence at the inquest, stated that he first attended the deceased in October, 1919, when he found him in the last stages of tuberculosis of the lungs, to which disease his death was due. He stated that his predecessor, Dr. Thompson, who had first attended the man, attributed the disease to the gas poisoning, and that the G.E.R. Company's doctor in London had accepted this [illegible] a cause of death. Dr. Hay had not known of a similar case before. The coroner's jury returned [illegible] verdict in accordance with the medical evidence.

Correspondence.

NAVAL MEDICAL MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—May I bring the following to the notice of any of your readers who may be interested. It is proposed to perpetuate, by a suitable memorial, the memory of the medical officers, nursing sisters, and men of the sick berth staff who were killed or died on service during the war. The memorial will be dedicated to permanent, reserve, and temporary officers, R.N. and R.N.V.R., and permanent and reserve nursing sisters and sick berth staff.

The final decision as to what shape the memorial will take will be in strict accordance with the wishes of the majority of the subscribers to the memorial fund, provided that the amount received will be sufficient for the purpose.

Those of your readers who have not already received a letter on this subject, and who may wish to subscribe, are invited to write to the Honorary Secretary, Naval Medical Memorial Fund, Medical Department, Admiralty, who will forward a copy of the original letter that has been circulated amongst those whose addresses are still on record at the Admiralty.

I am Sir, yours faithfully,

C. K. BUSHE,

Surgeon Commander, R.N., Honorary Secretary.

Admiralty Medical Department, 1 Lake Buildings,
St. James's Park, S.W. 1, March 23rd, 1920.

SLEEPING SICKNESSES.

To the Editor of THE LANCET.

SIR,—With the general tenor of your annotation on the above, which appeared in THE LANCET of March 13th, I think we must all agree; the public, as well as the profession, want a simple, popular name for lethargic encephalitis. Your annotation, however, contains one sentence referring to me, personally, with which I must respectfully beg to disagree. It is there suggested that the recent misuse of the term "sleeping sickness" by the lay press to designate cases of lethargic encephalitis can be traced to a remark made by me at the discussion held at the Royal Society of Medicine in October, 1918. It is, of course, gratifying to think that anyone, especially a member of the lay press, has remembered my words so long, even though, by taking them from their context, their meaning has been entirely misconstrued. I am afraid, however, that there is a more simple and probable, but less flattering, explanation. This abuse of the term "sleeping sickness" by the lay press only began a few weeks ago, so far as my information goes, whereas the discussion at the Royal Society of Medicine took place 18 months ago. I cannot think that any journalist has troubled to rummage amongst the old records of the Society's proceedings to find a term which, in connexion with African news, stares him in the face almost every week in his own columns. It is there he has seen it, found it "appropriate," and, with the journalistic eye for a good headline, laid hold of it without troubling to inquire whether it was already "appropriated" or not. Others have merely followed this smart lead. Unless the writer of your annotation has some definite proof that his theory is the correct one, I shall hold to the opinion that mine is much the more probable, and decline to believe that I am responsible, in the slightest degree, for the present "terminological inexactitude" in the lay press. I apologise for having taken up so much of your valuable space on a personal matter, but as my name has, quite needlessly I think, been introduced, I cannot allow it to stand unanswered. The question of much greater interest is, "What is to be done to put things right?" As popular names "Nona" or even "R(h)aphania" (vide THE LANCET, March 20th) seem peculiarly unsatisfying, whilst, for our own professional use, we have already a sufficiently unsatisfactory name, "encephalitis lethargica." Why change it? Personally, I hope we shall retain it until the bacteriologists provide us with such data as will lead to a permanent name of real value.

It is, however, desirable that we should have an alternative or popular name which we can use in dealing with the public. It is very inconvenient to have to say, "Your child is suffering from lethargic encephalitis." It is cumbrous and unintelligible, not to say alarming. In my experience it is usually met by the rejoinder, "Will that be the new disease we've heard so much about, doctor?" Now, it is obvious that we cannot go on calling it the new disease much longer; besides, according to some authorities, it is not a new disease at all and never has been!

Your annotation puts the position very well, and I cannot do better than quote it: "It remains for those who are concerned for an informed and accurate public opinion on health matters to devise some popular term for encephalitis lethargica less cumbrous than 'lethargic encephalitis' and free from the objection to 'sleeping sickness.'" Such a popular term should contain some reference to one or more of the salient features of the disease; it should avoid committing us to any views as to ætiology or pathology, and it should have some precedent in the popular nomenclature of allied conditions. I therefore humbly submit to the consideration of my colleagues the term "sleeping palsy" as an alternative or popular name for "encephalitis lethargica." It meets all the requirements I have mentioned. We have excellent precedents in the popular terms, "shaking palsy" for paralysis agitans, and "infantile palsy" for acute poliomyelitis. In fact, to some, "sleeping palsy" would only be the name for an atypical case of "infantile palsy"! I cannot think that the term I suggest would lead to any real confusion with true "sleeping sickness" (trypanosomiasis) any more than "infantile palsy" causes confusion with "infantile diarrhœa."

With their usual acumen the lay press have realised that a name, which contains the word "sleeping," meets their requirements, and have purloined the first they came across. We cannot punish them for their crime, but by a judicious process of barter we can make it innocuous. If they will give up the "sickness," which they do not want, we will give them, in place of it, the "palsy," which will suit them as well, and they can keep the "sleeping," which they will probably do anyhow! If this suggestion is approved, the full terminology, at present, would be "encephalitis lethargica, or sleeping palsy."—I am, Sir, yours faithfully,

Sheffield, March 21st, 1920. ARTHUR J. HALL.

BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—I have read, with great interest and entire approval, Major W. H. Broad's letter in your issue of March 6th, with reference to blind masseurs and masseuses treating patients by remedial exercises and muscle re-education. I do not feel, however, that he has fully answered the last part of your article of Feb. 21st, which states that "teachers of massage would do well to make this clear to their blind pupils"—viz., that the blind administrator is handicapped, and, unless this limitation is recognised, he or she will be tempted to mete out to patients inferior treatment. As a medical practitioner holding the Teacher's Certificate of the Inc. Soc. Trained Masseuses, and having several years' experience of teaching both blind and sighted men and women students, I should be very grateful if you would allow me to express my opinion that a well-trained, well-educated, blind masseur or masseuse is fully competent to give remedial exercises and muscle re-education. I have had many opportunities of observing the results of their treatment of patients under my care, and these results invariably have been most excellent. This being my experience, I am justified in continuing to impart to my blind students the same amount of knowledge that I do to my sighted students, telling the blind that they are not to think they have any limitations. I have taught blinded officers and men, with a perfectly clear conscience, during the five years that St. Dunstan's has been open. I never allow an exercise to be imperfectly performed on account of blindness, and I expect—and get—the same degree of perfection from the blind as from the sighted.

I am, Sir, yours faithfully,

Nottingham-place, W., March 16th, 1920. AGNES KEEN.

To the Editor of THE LANCET.

SIR,—The question raised in your annotation of Feb. 21st as to what extent blind men are capable of undertaking treatment of cases with Swedish remedial exercises is an interesting one. Major W. H. Broad states (THE LANCET, March 6th) that "blind men can apply any of the exercises described by Kleen, Wide, or any other disciple of Ling," and this, I think, will not be doubted by anyone who has noticed the adaptability of the unfortunate blind.

At the same time it is quite clear to those who have actually practised Swedish remedial exercises that something more definite is required for successful treatment than mere application of movements—namely, a *keen observation*. This is a particularly important factor in the treatment of deformities of the chest and spine where a constant watch on the patient is necessary. It will be argued that a blind man's touch makes up for his loss of sight; his touch is wonderful, but with both hands engaged in applying exercises he will be unable to make use of it during treatment; the loss of sight will thus handicap him in controlling the position of his patient. In chronic nervous diseases where incoördination is often the chief trouble, free movements in steady progress form an important part of the treatment, and it may be asked how the blind man is to know whether these movements are executed satisfactorily or not.

I feel sure that motives such as these guided the Incorporated Society of Trained Masseuses in their decision to exclude the blind masseur from their S.R.E. examination. But there is no need for lament, for the blind man who possesses the massage diploma has a great field for his ability. The after-treatment of fractures, of infantile paralysis, and the like, will provide scope for his acute touch.

The one difficulty which I foresee is that after 1922 the society will only give a conjoint diploma in massage and remedial exercises. Perhaps the massage diploma might be retained for a few years for the benefit of the blind, who deserve all the sympathy and help that can be given them.—I am, Sir, yours faithfully,

C. WESTMAN.

Brunswick-place, Harley-street, W., March 16th, 1920.

WOMEN'S MEDICAL SERVICE IN INDIA.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a leading article in THE LANCET of Nov. 1st, 1919, on the Women's Medical Service for India. May I comment on one or two statements in this article?

In the first place there is a quotation (p. 790) which is given as from the main report of the Women's Medical Service for 1918, but which is really a quotation from a report written by Dr. Catherine Wickham, who was directed by the Central Committee of the Dufferin Fund, with the consent of the Surgeon-General of Bengal, to visit and report on hospitals in Bengal under women medical subordinates. These hospitals are not in any way connected with the Central Committee of the Countess of Dufferin's Fund or the Women's Medical Service. They are under the Surgeon-General of Bengal and the municipal authorities in the various towns, who alone have any power to improve the conditions. The same is true of the conditions revealed in the report of Dr. Agnes Scott, W.M.S., assistant to the Inspector-General of Civil Hospitals, Punjab. The Central Committee of the Dufferin Fund is only connected with the hospitals of the Women's Medical Service (19 in number), and even for these has no administrative powers, and can only influence the local authorities by its power of removing the medical women lent from the Women's Medical Service. This has been done in two cases where the conditions made a good standard of work impossible. The reports so published, therefore, should not be used to discredit the Women's Medical Service, of which both the administrative body and many individual members are doing all in their power to improve the work of women subordinates.

Later in your article surprise is expressed that stress is not laid on the need for a nursing service parallel to the Women's Medical Service. As a matter of fact, such a service has been under consideration, and this year the first step has been taken in the organisation of a Dufferin Nurses Examining Board, which lays down uniform standards for Anglo-Indian and Indian nurses and arranges for examinations, certificates, and registration. But during the last five years it has been impossible to think of organising any women's services except those required by the war. The existing services have been maintained with difficulty and the nursing question has been especially acute owing to the large numbers of nurses employed in war hospitals. The Central Committee has taken care that every one of the hospitals under members of the Women's Medical Service has a matron qualified as a nurse and a staff of Indian or Anglo-Indian women under her. Lectures are given, examinations are held, all have regular turns of duty, and although, no doubt, in many cases the nursing is rough or inefficient as compared with English hospitals the patients are not neglected. There is no such arrangement in the majority of civil hospitals in India.

You state at the beginning of the report that the map is so thickly dotted with hospitals as to suggest camouflage when compared with the written report. You have not perhaps noticed the "References" below the map, which state that only those marked in red are hospitals under members of the Women's Medical Service. Those marked in blue are missionary hospitals, and those marked in green hospitals under local authorities. With the last two classes the Central Committee has nothing to do, but the information is given in the map because it is of service to the public generally to be able to see which parts of the country are most urgently in need of medical aid. You state that from the teaching schools there are "pathetic lists of scholarships and prizes awarded with ever-lowering standards." Facts, however, show that the standard of work of indigenous medical women is improving enormously. While in the year 1909 only 23 women were taking the University courses in medicine and 98 the "practitioner class" course (unregistrable), in 1918 161 women were taking University courses and 30 the "practitioner class" course.

Lastly, I come to the statement that "the development of the Women's Medical Service in India during the last seven or eight years shows little progress, indeed ...... a relative retrogression is displayed." May I draw your attention to the following improvements initiated by the Central Committee since 1914, the year when the service was founded?

1. Experienced members of the Women's Medical Service have been appointed to act as assistants to the Inspectors-General of Civil Hospitals for the inspection of women's hospitals in the Punjab and United Provinces.

2. Qualified medical assistants have been engaged in all the hospitals of the Women's Medical Service and qualified nurses as matrons.

3. A member of the Women's Medical Service has been appointed as Joint Secretary of the Fund to visit all members of the Women's Medical Service periodically and inform the Central Committee regarding their conditions of work.

4. Of the 19 hospitals under members of the Women's Medical Service four have been completely rebuilt on modern lines. Four more have funds in hand and are about to be completely rebuilt. Six others have had very important additions and improvements made.

5. The organisation of the Dufferin Nurses Examining Board already mentioned.

6. The Central Committee has applied to Government for, and received, grants (*a*) for the establishment of a school for training health visitors and midwife supervisors in Delhi; (*b*) for the establishment of a system of well-trained midwife inspectors in a number of selected centres in India, all under the inspection of a member of the Women's Medical Service; (*c*) for the organisation of courses of post-graduate instruction for medical women in India on the newer methods of treat-

ment of venereal diseases. The two first are already in working order, the third is now being organised.

7. The Central Committee has published in 1918 a special report on "Improvement of the Conditions of Childbirth in India" and in 1919 a report on "Venereal Diseases among Women in India." This last contained confidential information, and was therefore circulated privately only.

It must be remembered that the Central Committee has only had a subsidy of £10,000 a year for the Women's Medical Service, and that owing to the demand for medical women in the war it has had extreme difficulty in keeping the service up to strength.

I am, Sir, yours faithfully,
M. I. BALFOUR, M.B., C.M.,
Joint Secretary, Countess of Dufferin's Fund.
Delhi, Dec. 24th, 1919.

⁂ Dr. Balfour has misread the title of our article, which dealt generally with the medical service of women in India. With regard to our use of Dr. Wickham's report, in the main report, which Dr. Balfour signs, it is stated: "The Central Committee from the many inspection reports in its own office can fully endorse the remarks made by Dr. Wickham and Dr. Scott, which apply to practically every part of India." Our criticisms were directed, not against the Women's Medical Service of India, or the work of the Lady Dufferin Fund, but against the difficulties under which they are placed. And it was our appreciation of these difficulties that prompted the plea for a State Service of women with conditions of local prestige, pay, and leave more nearly approaching those of the Indian Medical Service. Should such a change come about we have no doubt that the Government of India would avail itself of the extensive organisation of the Lady Dufferin Fund.—ED. L.

MYALGIC PAINS AND MANIPULATION.

To the Editor of THE LANCET.

SIR,—With regard to Mr. R. C. Elmslie's letter on this subject in your issue of to-day's date, I am only too conscious of the assistance given to me by Mr. Elmslie himself, and other orthopædic surgeons in the treatment of cases, to be in anyway unmindful of my obligations towards them—their special skill and ability are not questioned. The point is whether there is *anything* to be learned outside the ranks of the profession. Unless I am mistaken, an offer was made to demonstrate cases before a committee of surgeons; had this offer been accepted the whole matter would have been settled.—I am, Sir, yours faithfully,

W. H. CLAYTON-GREENE.
Wimpole-street, W., March 20th, 1920.

To the Editor of THE LANCET.

SIR,—The correspondence under this heading has wandered wide since its opening. Mr. R. C. Elmslie, in your issue of March 20th, endeavours to show the fallacy of the "myth" that a bone-setter possesses some mechanical skill denied to the regular surgeon, or, at any rate, to the regular orthopædic surgeon. But with all respect I submit that a fallacy cannot be demonstrated by begging the whole question. Mr. Elmslie first gives the simple rules which govern the practice of the bone-setter. They are only two: first, restore mobility; second, restore the muscular power. Then he says: "Patients with derangement of the knee-joint should only be submitted to operation when continued locking of the joint takes place in spite of the fact that mobility is full and the muscles strong." I entirely misconceive the issues, unless I am right in believing that cases of this kind are precisely the cases that bone-setters profess to cure, and further, I, and many more of my profession, believe that we have personal knowledge of cases within this category which bone-setters actually have cured. Yet Mr. Elmslie says operation only.

Mr. Haldin Davis thinks that it is consonant with the dignity of the Royal College of Surgeons to appoint a committee of investigation to see if the case is as extremely simple as Mr. Elmslie suggests. I entirely agree with him. Certain it is that the matter cannot be settled by an invocation to Dr. Wharton Hood. I am old enough to remember that during his lifetime Dr. Wharton Hood was looked upon as hardly respectable. He wrote a large book in two volumes, a book almost forgotten. I should be surprised to hear that its precepts ever became a recognised basis of practice.

I am, Sir, yours faithfully,
Felixstowe, March 22nd, 1920. C. G. HAVELL.

ANÆSTHETISTS' FEES.

To the Editor of THE LANCET.

SIR,—Mr. H. Bellamy Gardner's letter in your issue of March 20th, with which I entirely agree, will serve a useful purpose if it leads to some understanding as to what fees special anæsthetists should now be entitled to charge. If it is admitted that their pre-war scale of fees was not excessive, it is obvious that the same rate of payment must be totally inadequate now, in view of the enormous increase in the cost of living.

The practice of anæsthetics as a specialty has an appreciable influence upon surgical results, and it is in the public interest that the fees of a whole-time anæsthetist should be sufficiently generous for him to earn a good living. Unless it is recognised that this is impossible on the pre-war scale, specialism in anæsthesia will gradually be starved out of existence.

In most districts general practitioners have met and agreed to raise their fees in some definite ratio. Why should anæsthetists not do likewise?

I am, Sir, yours faithfully,
J. HENRY CHALDECOTT.
Harley-street, W., March 22nd, 1920.

A PERMANENT ARMY DENTAL CORPS.

To the Editor of THE LANCET.

SIR,—The Executive Council of the Federation of Medical and Allied Societies has, at the request of the British Dental Association, addressed a letter to the Medical Committee of the House of Commons, as well as to the medical Members of Parliament who are also members of the Federation, asking for support of the proposal of the Secretary of State for War, issued in explanation of the Army Estimates, that a permanent Army Dental Corps should be instituted. That this proposal may be rejected or curtailed in Committee on the grounds of economy is regarded as possible by the British Dental Association. The formation of such a corps was the subject of a scheme submitted by the British Dental Association at the request of the War Office in August, 1919, and it is felt that the interests of national health are concerned in ensuring that the recommendations of the Secretary of State for war, which constitute the minimum on which an effective dental service can be established, are given effect to.

I am, Sir, yours faithfully,
N. HOWARD MUMMERY,
General Secretary.
The Federation of Medical and Allied Societies, 5, Vere-street, Cavendish-square, London, W. 1, March 20th, 1920.

PARAPHRENIA.

To the Editor of THE LANCET.

SIR,—Far be it from me to put a spoke in the wheel of progress; but I would like to suggest that the term "chronic hallucinatory psychosis," introduced by Dr. R. H. Steen, and mentioned in your issue of last week, should be forthwith expunged: (*a*) because the term is applicable to many varieties of mental disease and is therefore liable to create confusion; and (*b*) because the disorder to which Dr. Steen refers has already received the name "paraphrenia." Following Kraepelin, I have described the malady under this designation in the last edition of "Mind and its Disorders." As Dr. Steen's "acute hallucinatory psychosis" includes also some cases of melancholia (*sic*) and some of dementia præcox, the term stands self-condemned.

My chief reason for this letter, however, is that Dr. Steen and some other speakers at the discussion of his paper recommended psychoanalysis as a mode of treatment for this malady. Having had some psychoanalytic experience of paraphreniacs, I wish to utter a warning that the resistances, which are already very strong in these patients, become increased on psychoanalysis, that the ultimate result is unfavourable, and, therefore, that this mode of treatment is not to be recommended or attempted for such patients.

I am, Sir, yours faithfully,
W. H. B. STODDART.
Cavendish-square, W., March 23rd, 1920.

THE CULTIVATION OF THE MENINGOCOCCUS.

To the Editor of THE LANCET.

SIR,—Dr. H. Stanley Banks's article in THE LANCET of March 13th on the Serum Treatment of Cerebrospinal Fever is of considerable interest. The cultivation of the meningococcus is, however, not always such a simple process as Dr. Banks suggests. "Coagulated blood serum" is, of course, a very suitable culture-medium, but in many instances gives no growth until incubated for 48 hours, and occasionally fails altogether even when the usual precautions, as mentioned by Dr. Banks, are taken. Hence it is a frequent occurrence that one is unable to report on the type of organism for two–three days after first seeing the patient. Obviously this is a serious drawback if the clinician wishes to administer the homologous serum at once.

My experience *re* agglutination is that the macroscopic is the most reliable, and that Gordon's type sera are useless for the microscopic method. Theoretically, one should administer the homologous serum in any given case, but in practice I am not at all satisfied that it is a matter of great moment. I have examined many of the Lister sera for agglutinins to Gordon's four types of meningococci, and have found that each type serum agglutinates each type of coccus up to a varying titre—i.e., type 1 serum agglutinates not only type 1 coccus but also types 2, 3, and 4—similarly with type 2 serum, and so on. Type 4 coccus is extremely rare, so I always administer a mixed serum of type 1 and type 2. As type 3 coccus is so closely related to type 1 coccus, this mixed serum does well in type 3 infections. Before using this mixed serum one naturally must demonstrate to oneself that agglutinins for all three types are present.

I am, Sir, yours faithfully,
WILLIAM A. MUIR.
Wallasey, March 17th, 1920.

ANÆSTHETICS AND DIABETES MELLITUS.

To the Editor of THE LANCET.

SIR,—As a student I was taught that there was considerable risk in administering chloroform to patients suffering from diabetes mellitus. Fatal coma developed frequently within a day or two of the anæsthesia. This teaching was the result of experience and correct as far as it went, but since that time much has been added to our knowledge of diabetes mellitus. We have known for some time that when suitable precautions are taken the risk of post-operative coma is comparatively small. We know, too—but perhaps it is not known to all, hence the object of this letter—that the administration of any general anæsthetic, such as chloroform, ether, and nitrous oxide with oxygen, may lead to a comparatively slight case of diabetes mellitus developing into one of great severity.

It is only during the last five years that it has been possible to determine the gravity of any case of diabetes mellitus, because the mere percentage of sugar in the urine or the total quantity of dextrose excreted daily is no gauge to the extent of the alteration in the metabolism. Evidence seems to be accumulating that diabetes mellitus is due to a change in the interacinary cells in the pancreas; that the severity of the disease depends upon the number of cells destroyed; that the condition which has destroyed some cells has diminished the vitality of others, and these may be killed by various toxins brought to them in the blood, amongst them chloroform, ether, and nitrous oxide, and in all probability those elaborated by micro-organisms such as cause scarlet fever, pneumonia, measles, influenza, &c.

The observations upon which this conclusion is based are of the following type: A man suffering from diabetes mellitus, who excretes diacetic acid and β-oxybutyric acid along with a considerable quantity of sugar whilst on a diet extremely poor in carbohydrates, but rich in protein and fat, may be found to lose his glycosuria and all evidence of acidosis on a diet, say, of 50 g. carbohydrate, 60 g. protein, 180 g. fat. This diet possesses sufficient energy to allow the individual to maintain his weight and do as much work as is necessary to earn a living by manual labour. This man has an accident and breaks his arm. An anæsthetic is administered to permit the arm being placed in the best position. After the anæsthetic sugar is found in the urine, and persists. Upon reinvestigating the maximum diet which will control glycosuria it is found that it has fallen to 20 g. carbohydrate, 60 g. protein, and 100 g. fat. Often the deterioration in the metabolism is much greater than this. The patient can no longer remain on a diet which allows his urine to be free from sugar and permits him to retain his weight and live a useful life. He is, therefore, forced to disregard his disease, eat more or less what he likes, and he develops coma at a comparatively early date. The unnecessary anæsthetic may have shortened his life by years.

I quite realise that the presence or absence of sugar in the urine is not the best method of determining the optimum diet, but one which permits the majority of medical men making an attempt to do their best for the patient. In my opinion at the present day students should be taught that only operations that are absolutely essential should be performed upon diabetics; that spinal anæsthesia and local anæsthesia should be adopted when possible; that nitrous oxide with oxygen is less likely to damage the patient than ether, and ether is less likely to do harm than chloroform.

I am, Sir, yours faithfully,
O. LEYTON.
Portland-place, W., March 19th, 1920.

AFTER-EFFECTS OF MALARIA.

To the Editor of THE LANCET.

SIR,—I have been very much struck during the last 18 months while examining soldiers on their discharge, and after their discharge, when claiming for pensions, by the abnormal number of cases of thickened arteries occurring in men between the ages of 20 and 28, who have suffered from malaria during some period of their service. Many of these cases apparently have only been of mild type, some have been undergoing quinine treatment for prolonged periods, others have not.

I should be very glad to hear if this experience has been shared by other members of medical boards especially.

I may say that an examination of urine in these cases has been a routine, and the condition of arteries apparently exists in subjects which show no signs of, and in whose history there is no evidence of, albuminuria.

I am, Sir, yours faithfully,
A. HURRELL STYLE, M.D.
Ministry of Pensions, Headquarters, Suffolk Area,
Church House, Bolton-lane, Ipswich, March 17th, 1920.

THE GENESIS OF TWINS.

To the Editor of THE LANCET.

SIR,—In a recent number of *Genetics*[1] I have presented statistical evidence which shows, I believe conclusively, that it is far more probable that twins form a homogeneous group of uniform origin than that they are of two distinct types—"fraternal" and "identical." Dr. Thorndike's data are, I believe, the only extensive body of measurements of twins, and from his data it appears that (1) the variation in resemblance agrees closely with the variations due to sampling on the hypothesis of uniform origin, and is materially less than it would be for dual origin; (2) twins most alike in any one trait are not more alike than other twins in other traits.

In view of these facts the genesis of twins becomes a new problem, and I have ventured to put forward the hypothesis that twins arise from identical ova fertilised by different spermatozoa. Physiological evidence is probably beyond our reach; genetic evidence is, however, sufficient to prove or disprove this suggestion. If it be true, twins who differ in any Mendelian character must have a heterozygous father. In the comparatively few cases which I have so far collected, which include eye colour, osteopathyrosis, and colour-blindness, it has, in fact, been the father and not the mother who is heterozygous. Extensive pedigree material is being searched for similar cases, and it is in order to make a wide appeal to physicians that I beg the indulgence of your space.

---

[1] Princeton University Press, September, 1919.

Eye colour, being, I believe, the only normal human trait which is certainly Mendelian in inheritance, naturally supplies the great majority of the cases. I therefore add a simple tabular form in which complete information as to a single family may be included :--

—	Father.	Mother.	Twins.	Brothers.	Sisters.
Simplex ...		1	1	2	1
Duplex	1		1	1	2
Unknown ...				1	

Simplex stands for the complete absence of yellow or brown pigment from the iris; *duplex* stands for its presence, as in black, brown, and hazel eyes.

I am, Sir, yours faithfully,

R. A. FISHER,
Statistician.

Statistical Laboratory, Lawes Agricultural Trust, Rothamsted Experimental Station, Harpenden, March 22nd, 1920.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. F. E. Gunter relinquishes the temporary rank of Colonel.

Lieut.-Col. W. J. Taylor retires on retired pay.

Major D. Ahern relinquishes the temporary rank of Lieutenant-Colonel.

Major A. C. Osburn relinquishes the acting rank of Lieutenant-Colonel.

The undermentioned relinquish the acting rank of Major: Capt. and Bt. Major T. A. Weston; Capts. R. H. Lucas, L. S. C. Roche, S. H. Smith, W. T. Graham; Temp. Capts. C. B. Davies, R. B. Roe, E. J. Maxwell, P. McCool, F. O. Clarke, L. Anderson.

To be acting Majors: Capt. and Bt. Major W. F. Christie; Capt. W. B. Rennie; Temp. Capt. C. B. Jones.

Capt. J. W. G. H. Riddel resigns his commission.

Capt. J. E. Hepper is seconded for service with the Egyptian Army.

M. J. Whelton to be temporary Captain.

Temp. Lieut.-Col. G. S. Jackson (Major and Bt. Lieut.-Col., 7th North'd Fus., T.F.) relinquishes his temporary commission.

Officers relinquishing their commissions:—Temp. Major J. L. Maxwell (retains the rank of Major). Temp. Capt. H. C. Gibson (granted the rank of Major). Temporary Captains retaining the rank of Captain: H. S. Sugars, R. A. C. Rigby, H. L. S. Griffiths, J. A. R. Thompson, T. S. Goodwin, A. R. Jennings, W. Weir, H. M. Wilson, W. J. Thomas, R. K. H. Gillespie, W. C. Mayo, A. H. Manfield, A. Leitch.

GENERAL RESERVE OF OFFICERS.

Captains relinquishing their commissions: F. Oppenheimer and H. B. Sherlock (retains the rank of Captain).

SPECIAL RESERVE OF OFFICERS.

Captains relinquishing their commissions and retaining the rank of Captain: P. A. O'Brien and C. S. Parker.

TERRITORIAL FORCE.

Capt. (acting Lieut.-Col.) J. M. A. Costello relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capt. (acting Major) W. Applevard relinquishes the acting rank of Major on ceasing to be specially employed.

West Lancashire Divisional Sanitary Section: Capt. A. Reid is seconded.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are transferred to the unemployed list: Capt. W. H. Anderson; 2nd Lieut. H. W. Boot.

Capt. J. J. Sinclair relinquishes his commission on account of ill-health contracted on active service, and is permitted to retain his rank.

INDIAN MEDICAL SERVICE.

Capt. T. D. Murison to be temporary Major.

THE HONOURS LIST.

Temp. Lt.-Col. R. J. Norris, R.A.M.C., has been appointed a Commander of the Most Excellent Order of the British Empire, for valuable services rendered in connexion with the war.

The name of Surg. Lt. H. C. C. Joyce, R.N., has been mentioned in despatches.

FOREIGN DECORATIONS.

American.

Distinguished Service Medal.—Lt.-Col. and Bt. Col. Sir E. S. Worthington, Kt., K.C.V.O., C.B., C.M.G., R.A.M.C.

Belgian.

Ordre de la Couronne.—Officier: Temp. Maj. C. Christy, R.A.M.C.

Ordre de Leopold II.—Commandeur: Lt.-Col. Sir D. Prain, Kt., C.M.G., C.I.E., F.R.S., I.M.S. (ret.).

Médaille du Roi Albert.—Capt. O. R. Horwood, Austr. A.M.C.

Egyptian.

Order of the Nile.—4th Class: Surg. Comdr. J. Thornhill, R.N.

French.

Légion d'Honneur.—Officier: Maj. D. L. Fisher, D.S.O., R.A.M.C. (T.F.).

Croix de Guerre.—Capt. W. Donald, M.C., R.A.M.C. (S.R.); Temp. Capt. H. L. Messenger, M.C., R.A.M.C.

Ordre de l'Etoile Noire.—Officier: Maj. J. H. Barbour, R.A.M.C.

Médaille d'Honneur avec Glaives (en Vermeil).—Capt. W. V. Corbett, R.A.M.C.

Médaille des Epidémies (en Argent).—Capt. and Bt. Maj. R. E. Kelly, C.B., R.A.M.C. (T.F.); Capt. J. F. Roberts, R.A.M.C. (T.F.).

Hedjaz.

Order of El Nahda.—4th Class: Temp. Capt. G. C. Ramsay, R.A.M.C.

Italian.

Order of the Crown of Italy.—Commander: Col. C. A. Hodgetts, C.M.G., Can. A.M.C. *Officer:* Maj. C. Bramhall, O.B.E., R.A.M.C. *Cavalier:* Capt. P. R. Bolus, R.A.M.C. (T.F.).

Japanese.

Order of the Rising Sun.—3rd Class: Surg. Capt. G. T. Broatch, C.B.E., R.N.

Portuguese.

Military Order of Aviz.—Commander: Capt. J. W. McNee, D.S.O., R.A.M.C. (S.R.); Col. A. D. Sharp, C.B., C.M.G., A.M.S. (T.F.).

Serbian.

Order of St. Sava.—5th Class: Capt. C. G. Skinner, R.A.M.C. (T.F.).

THE MEDICAL SERVICES IN AFGHANISTAN.

IN a despatch dealing with the operations against Afghanistan, commencing in April, 1919. the Commander-in-Chief in India makes the following references to the medical services:—

> As regards the Medical Service, the number of regular R.A.M.C. and I.M.S. officers available in India was short of our requirements for complete mobilisation. The source of recruitment of these categories in India is small, and it had been found impossible to make good the deficiency from home. I was fortunate, however, in obtaining the services of 107 officers and 1280 other ranks of the R.A.M.C. who happened to be in India en route from Mesopotamia to the United Kingdom. The field medical units of the field army were already partially mobilised with personnel when the outbreak of war occurred, and the equipment of other field medical units and of 21 general hospitals was held ready for issue in medical mobilisation stores. The number of mobilised medical units employed during the campaign amounted to 29 field ambulances, 12 casualty clearing stations, 53 staging sections, 15 sanitary sections, 8 advanced depôts of medical stores, 1¼ base depôt medical stores, and 16,000 beds in general hospitals—i.e., 5000 for British and 11,000 for Indians. The general hospitals were established at Landi Kotal, Peshawar, Nowshera, Rawalpindi, Gharial, Kuldana, Kohat, Bannu, Dardoni (near Miranshah), Dera Ismail Khan, Tank, Manzai, and Quetta. In addition to these, convalescent camps provided accommodation in the Murree Hills for 1200 British at Upper Topa and Lower Gharial and for 3000 Indians at Kohat and Rawalpindi. Medical transport included two British and eight Indian broad-gauge ambulance trains, one combined British and Indian narrow-gauge ambulance train, and over a hundred specially fitted railway ambulance coaches for use with the ordinary passenger service.
>
> The two outstanding features of the campaign from the medical point of view were, firstly, an outbreak of cholera of unusual severity, and, secondly, the abnormal climatic conditions under which the troops were called upon to operate. An epidemic of cholera, seldom equalled in extent and severity during the past ten years, was raging among the civil population of the Punjab and North-West Frontier Province during the period of the operations. It first made its appearance among the troops in the forward areas at Hangu on June 1st and at Jamrud on June 4th, but though it spread rapidly in both the Kohat and Khaibar areas and for a time gave rise to grave anxiety, it was successfully stamped out by June 20th, an achievement for which the Medical Service deserves the greatest credit. A severe epidemic also occurred in Derajat and the Tochi Valley, and cases continued intermittently from the middle of June till the close of the operations.
>
> Shortly after the outbreak of hostilities a heat wave of remarkable severity occurred over the whole of the Punjab and North-West

Frontier Province, the daily shade temperatures registered at Peshawar in May, June, and July being 5° to 7° F. above the daily average of the past 20 years. The Government of India will appreciate how great a strain was imposed on the troops when called upon to operate under these conditions in such areas as the Khaibar, the Kurram, the Derajat, and Waziristan.

In spite of these conditions the incidence of sickness was not excessive. The total admissions during the period May 5th to August 9th amounted to 10,882 British and 45,774 Indians, giving a daily admission-ratio per 1000 of 4·98 British and 2·97 Indians. This compares not unfavourably with admission-ratios in Mesopotamia, which in 1917 were 5·04 and 2·11 and in 1918 3·48 and 2·27 respectively.

The Commander-in-Chief also states that the energy and promptness displayed in dealing with an outbreak of cholera reflect the greatest credit on the Medical Service, whose work throughout has been deserving of the highest praise.

THE CHADWICK GOLD MEDALS.

At the first of the three lectures on Military Hygiene in Peace and War, delivered on March 8th at the Royal Society of Arts by General Sir John Goodwin, Sir William J. Collins, chairman of the Chadwick trustees, presented the Chadwick gold medals and prizes of £100 to Surgeon-Commander Edward L. Atkinson, D.S.O., R.N., and Brigadier-General W. W. O. Beveridge, C.B., C.B.E., D.S.O., A.M.S., for services in promoting the health of the men in the navy and army. Surgeon-Commander Atkinson, who in 1909 began investigations into the use of vaccines in gonorrhœal rheumatism, formed one of the medical section of the Antarctic expedition under Captain Scott in 1913, and in the following year, when on a Colonial Office investigation into tropical diseases, contributed to the discovery of the life-cycle and mode of spread of *Schistosoma japonicum.* During the war he rendered valuable services in the prevention of disease caused by pests of flies. He has been awarded the Albert Medal for saving life on a burning ship, and a brief account of his gallant action was published in THE LANCET of May 24th, 1919, p. 915. Brigadier-General Beveridge was Assistant Director of Medical Services for Sanitation at General Headquarters during the whole period of the war, and was the initiator of the Divisional Sanitary Section in 1914. He was a member of many important committees for the investigation of disease and the conservation of food, was responsible for pure water-supplies in the field of operations in France, and invented several processes which greatly conduced to economy and efficiency in general sanitation during hostilities.

DEATHS IN THE SERVICES.

Deputy Surgeon-General C. A. Innes, A.M.D. (retired), died at Lynwood, Charmouth, Dorset, in his eighty-ninth year, on March 17th. He received his first commission in 1855, and was present at the siege and capture of Sebastopol (medal with clasp, and the Turkish medal). In 1856 he joined the 52nd (Oxfordshire) Light Infantry and proceeded with this regiment to India, where he was present at the siege and assault of Delhi, his regiment furnishing the storming party of the Kashmir Gate (medal, and promoted in recognition of his services). He also served for many years with the 16th (Queen's) Lancers.

Obituary.

NATHANIEL PAINE BLAKER, M.R.C.S., L.S.A.

ALTHOUGH he had long given up active work, Mr. Nathaniel Paine Blaker, who died at Cherington, Hurstpierpoint, on March 12th, will be widely mourned, particularly in his native county of Sussex.

Born at Mays, Selmeston, in 1835, "Nat" Blaker, as he was affectionately known all through his life, left school at 16, and began to learn farming, but after a year's work, discouraged by the agricultural depression, he determined to enter the medical profession, and became a pupil at the Sussex County Hospital at Brighton. Three years later he went to Guy's, took his M.R.C.S. and L.S.A. in 1858, and was appointed assistant surgeon at the Convict Hospital at Lewes. From there he went with the invalid convicts to the newly-built model prison at Knapp Hill, Woking. In 1860 he returned to Brighton as house surgeon first to the Dispensary, and then to the Sussex County Hospital. On the termination of this appointment three years later he set up in private practice, and soon gained a large clientèle as a pioneer of the new Listerian methods. He had patients in all parts of the district, where, driving his own pair-horse phaeton, he became a familiar figure.

Mr. Blaker appeared in many famous cases, of which the most notable was the Brighton chocolate poisoning mystery. Called to several cases of sickness after eating fruit and chocolate, his suspicions led him to communicate with the police, with the result that a certain Miss Edmunds was arrested and was placed on trial. This woman had formed an insane attachment to a local medical man, and had conceived the idea of disposing of his wife. She sent anonymous presents of poisoned chocolate and fruit, and in the hopes of diverting suspicion contrived that poisoned chocolates should be mixed with the stock of a local confectioner.

Mr. Blaker was the author of a book of reminiscences entitled "Sussex in Bygone Days," describing the village life of last century, with its primitive habits and customs. The chapter on Altered Type of Diseases is of special interest. Mr. Blaker was impressed with the decline of vesical calculi, especially in children, of bone syphilis and tubercle, and with the increase of neurotic ailments. Of his experiences as surgeon to the prison at Lewes he says: "I learned also that men, even convicted felons, are not all bad, that some traces of good feeling are always to be found, and I must say I received as much gratitude, or even more, from convicts than from many others."

Although he had lived in retirement for 20 years Mr. Blaker's death leaves a notable blank in the county of Sussex, for his memory is still treasured by a large circle of old patients, friends, and colleagues. He was admired and respected alike for his medical knowledge, his sound judgment, and his intellectual honesty, while his kindness and friendly interest endeared him to all who came in contact with him. It was these gifts that enabled him to become—as undoubtedly he was—one of the most successful practitioners of his day.

GEORGE VICTOR PEREZ, M.B. LOND.

THE death from pneumonia of Dr. George V. Perez at his home in Santa Ursula, Tenerife, on Feb. 29th, removes a physician of international distinction. The descendant of a line of doctors, Dr. Perez received his training at University College Medical School, afterwards holding a resident appointment at the Brompton Hospital for Consumption. He graduated M.B. Lond. in 1883 and returned to Tenerife, where he was for many years the leading physician in Orotava. He was known to medical literature through his description of the characteristic sounds often yielded by fibrous mediastinitis—"Perez's sign." His clinical work combined great accuracy and observation with a special keenness for therapeutics. He was an early advocate of tincture of iodine for typhoid. He cherished a strong belief in the healing virtues of raw garlic for pulmonary and other affections. His latest therapeutic inquiry related to the beneficial action of eucalyptus in glycosuria and diabetes, following on the work of Dr. A. G. Faulds of Glasgow. For long his health had not been good. After undergoing a severe abdominal operation in London he did not completely recover his strength; and shortly he retired from practice. But his active mind never rested from the attempt to elucidate pathological problems. The medical profession loses in him an untiring student.

MORGAN DOCKRELL, M.A., M.D. DUB.

Dr. Benjamin Morgan Dockrell, who died in London on March 15th in his sixty-first year, was son of the late Thomas Dockrell, of Monkhouse, co. Dublin, and was educated at Cheltenham and Trinity College, Dublin, taking his clinical studies later at Dr. Steevens' and Adelaide Hospitals. Qualifying in 1882, he started in special dermatological practice six years later, and was for nearly 30 years on the staff of St. John's Hospital for Diseases of the Skin in Leicester-square, being senior physician and Chesterfield lecturer at the time of his death. During his period of service the hospital developed into a large skin clinic and became a centre of post-graduate teaching. He was intimately associated with the London Dermatological Society, presiding over its gatherings in 1912. He had been in failing health for two or three years, his death coming suddenly in the midst of his work.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 17TH.

Major DAVID DAVIES asked the Pensions Minister if medical men employed on medical boards had had their pay raised by 50 per cent., while medical men employed as assessors on sessional rates had had their pay raised by only 25 per cent.; if so, whether he would state for what reason this distinction was made.—Sir J. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: The answer to the first part of the question is in the affirmative, but the conditions of work of the medical board and the assessor are not the same, the members of the board being drawn from a panel, while the assessors are continuously employed.

Tuberculosis Expert on Medical Boards.

Mr. WILLIAM GRAHAM asked the Pensions Minister whether his attention had been directed to the fact that many discharged men suffering from tuberculosis in all parts of the country were being sent to ordinary medical boards for the re-assessment of their pensions; whether these pensions were, in many cases, being reduced; and whether he would take steps to ensure that an expert in tuberculosis should always be a member of a medical board when it dealt with the cases of men suffering from tuberculosis.—Sir J. CRAIG replied: Whenever a specialist's opinion is required arrangements are made to secure either that the tuberculosis officer of the district sits on the board, or that the man is referred to him for examination and report.

THURSDAY, MARCH 18TH.

Home Treatment of Disabled Men.

Mr. WALLACE asked the Pensions Minister whether he was aware of the dissatisfaction caused by one of the regulations of his Department which provided that before home treatment to disabled men recommended by the ordinary medical referee could be granted the recommendation might be cancelled by the D.C.M.S., who did not even see the disabled men; and what steps he proposed to take to remedy this.—Sir J. CRAIG replied: I am not aware of the dissatisfaction. The Deputy Commissioner of Medical Services may order hospital treatment instead of home treatment, but this occasions no hardship to the disabled man, who receives adequate allowances while in hospital, and also while awaiting admission. The Deputy Commissioner cannot, under the terms of the revised Circular 204, refuse allowances to a man accepted for home treatment without either having the man examined or obtaining the medical referee's concurrence.

Institutional Treatment of Tuberculosis.

Lieutenant-Colonel FREMANTLE asked the Minister of Health whether public health authorities were responding to the pressure he was putting upon them to provide further institutional accommodation for tuberculosis; whether such provision would require the diversion of labour and material from housing operations; and whether he would therefore require health authorities in the first instance to make full use for this purpose of any vacant accommodation in Poor-law infirmaries.—Dr. ADDISON replied: The answer to the first part of the question is in the affirmative. I am doing all that is possible to facilitate the use by public health authorities for the treatment of tuberculosis of vacant Poor-law accommodation, in so far as it is suitable for the purpose, but the need for further provision for this purpose cannot be wholly met in this way. I do not think that the limited and necessary amount of new building for sanatoriums will affect housing operations.

Small-pox at Poplar.

Mr. ROBERT YOUNG asked the Minister of Health whether he was aware that an attempt had been made to burn down Bells Wharf, at Bromley-by-Bow, by persons unknown; whether the apparent reason for this attempt was the retention on these premises of goods believed to contain small-pox infection; whether nothing had been done to remove these goods for destruction since the outbreak of small-pox there, which occurred three weeks ago; whether persons who had been in direct contact with small-pox infection had not been isolated, but allowed to go about freely and mix with the community generally; whether some of these contacts had since developed small-pox; whether houses in which small-pox cases had occurred had not been thoroughly cleansed by the stripping of walls and lime-whiting, as in previous outbreaks; and what action he proposed to take to compel the local authority to do everything within its power to prevent the spread of this diease.—Dr. ADDISON replied: I have no information as to the first two parts of the question, but I am informed that the goods referred to are now being removed from the wharf. I understand that in accordance with the usual modern practice, persons who are known to have been in recent contact with others who have since developed small-pox are offered free vaccination and are bathed and their clothes disinfected, and they are kept under daily observation by the medical officers of the borough council for a period of 16 days. I am advised that as a general rule the incubation period of the disease is 12 days, and that during that period the infection of the disease is not spread, but that should any person under medical observation exhibit symptoms of illness he would at once be isolated. The answer to the fifth part of the question is in the affirmative, but I should point out that of the five contacts who have developed small pox three refused vaccination. I am advised that the method of disinfection of houses which has been adopted in Poplar is considered satisfactory, and that the local authority are doing everything within their power to prevent the spread of the disease.

Welsh Board of Health.

Mr. ALFRED T. DAVIES asked the Minister of Health whether a woman had been appointed to the Welsh Board of Health; whether reorganisation had taken place due to the increased work under the new Ministry of Health Bill, under which the Welsh Board of Health had been reconstituted from the late Insurance Commission; if so, what, if any, responsible positions under the Board had been allocated to women; and whether appointments had been made in accordance with the first of the words used in Clause 6 of the Ministry of Health Bill that the Minister in making appointments of staff should give equal consideration to the suitability of persons of both sexes.—Dr. ADDISON replied: The reply to the first part of the question is in the negative. The organisation of the Board and staff of the Welsh Board of Health is not yet complete, and due consideration will be given to the points raised in the honourable Member's question.

Nursing Associations and the Ministry of Health.

Captain REGINALD TERRELL asked the Minister of Health if he would state what reasons had actuated him in refusing the request of the Council of the Queen Victoria's Jubilee Institute for Nurses that representatives of the county nursing associations and of the institute should be appointed on certain of the consultative councils under his Department.—Dr. ADDISON replied: The total membership of a consultative council is restricted by Order in Council to 20, and I regret that within this limit it was not found possible to include persons having the special type of knowledge and experience in question in the Council on Medical and Allied Services. I am hoping, however, to have the advantage of their assistance on any committee of the council appointed to consider the future organisation of nursing services.

FRIDAY, MARCH 19TH.

Dogs' Protection Bill.

Sir F. BANBURY, in moving the second reading of the Dogs' Protection Bill, said that similar Bills had been read a second time on three previous occasions. The present measure was in the form in which it left the Standing Committee last year. Although there was considerable opposition on the part of some medical men to the Bill, he claimed that the opposition was by no means unanimous. According to an article in THE LANCET in May last year, it would appear that the progress of medical science would not necessarily be interrupted if his Bill were passed. He was anxious to test the feeling of the House on that occasion, and he hoped, therefore, that there would be a division.

Sir WATSON CHEYNE moved that the House should refuse to proceed further with a measure which would impose an unnecessary and serious obstacle to medical research. Last year nothing, in his opinion, was said in support of the Bill, except that the dog was the friend of man. This was really a matter of sentiment, and he would ask Sir F. Banbury whether the limitation of the operation of the measure to dogs meant that he would permit experiments on other animals?

Sir F. BANBURY said that he was concerned only with the Bill before the House. If a Bill was brought in dealing with other animals he would deal with it then.

Sir WATSON CHEYNE, continuing, said that the Bill was really class legislation of the very worst kind. As a matter of fact, dogs only formed a very small proportion of the animals operated on. The return for 1913, which was the latest available, showed that out of a total of 88,000 experiments on animals only about 400 or 500 dogs were dealt with. The chief reason why the dog was used in experiments was that, more than any other animal, his physiological processes approached closely those of man. Another reason was that as the dog lived with man and was the friend of man he was more easily handled in experiments, being undisturbed by fear. The popular idea seemed to be that the moment a medical man saw a dog he cut it open to see what it looked like inside. The whole subject of an experiment was carefully thought out weeks beforehand, and then the animal which would yield the best results from it was chosen. In the course of years a great deal of surgery had been built up on experiments on dogs. For example, there were spinal surgery and the surgery of the brain. The idea of this Bill was to prevent painful experiments, but on this point he claimed that the measure was unnecessary. The great majority of the work done upon dogs did not cause pain. It seemed to him rather curious that an owner of a dog might save his money by giving it any food he chose, but if he wanted to find out what was the best kind of food he was obliged to have a licence. The largest number of experiments on dogs were feeding experiments, and these would be stopped by this Bill. He hoped when this Bill was brought forward again next year that its promoters would find a better phrase than "calculated to cause pain." It was utterly wrong, and "likely to cause pain" would be much better. In cases where an anæsthetic was used, and the anæsthetic was ultimately increased until the animal died, there would be no pain. Experiments of this kind had produced information of enormous value. It had been found that every muscle of the body was connected with a part of the brain. In the case of disease or injury the part of the brain which was the seat of the injury could be mapped out by the reaction of the muscles. This was done during the recent war. He was not prepared to say that there were no experiments which might not cause pain, but he had thought the matter out very carefully, and his view was that the number of experiments on dogs that were painful must be very few. For the last 30 or 40 years the anæsthetising of dogs had been quite perfect. The sight of the requisite apparatus for these experiments in catalogues of instruments and appliances led the uninitiated to regard them as instruments of torture. But in the performance of a delicate operation it was necessary to have the subject fixed, and somewhat elaborate arrangements were necessary for that purpose. It was not necessary to abolish experiments on dogs in order to save the animals pain. If it were considered necessary to have more frequent or even constant official inspection of experiments no one would raise the slightest objection. The successful transfusion of blood, by which the lives of many soldiers had been saved during the war, was entirely the result of experiments on dogs. Why was it that medical men and scientists all over the world were opposed to the principle of this Bill? It was absurd to think of men of high repute in science standing in dark corners to torture animals. The reason for their opposition was because they realised their ignorance, and that they did not know nearly enough to carry through their job successfully. They wanted more knowledge. They could not afford to allow any means of acquiring more knowledge slip past them. It had been stated that more people had died of influenza since the armistice than were killed during the Great War. Ten people died every hour of the day and night from cancer and tuberculosis. With such an appalling death-rate from diseases of which they knew nothing they could not afford to give up any possible sources of information. He believed that the solution of the problem of cancer would come through investigation on dogs. The House, in dealing with this matter, had human life in its hands, and if it passed this Bill it would assume a great responsibility.

Captain LOSEBY, in seconding the motion, said he did so, not because he loved dogs less, but because he loved his own kind more.

Sir J. BUTCHER, in supporting the Bill, contended that the present law did not prevent painful experiments.

Lieutenant-Colonel MOORE-BRABAZON said the medical profession might be very knowledgeable on the subject of physiology, but they were extraordinarily ignorant of psychology. If they eliminated the vivisection of the dog they would take the heart out of the antivivisection movement in this country. The medical profession was probably the most reactionary trade-union that existed. If they would let this Bill go through there would be no opposition to vivisection of other animals.

Captain ELLIOT described the Bill as a pettifogging measure to obstruct as far as possible the progress of medical science. In rejecting the Bill last year the House performed a service of the utmost importance to humanity. Researches which began immediately after its rejection, and which would have been stopped if it had passed, had led to great scientific results and would lead to many more. The dog was the only animal upon which experiments in relation to the heart could be carried out. As a result of those experiments they were already beginning to find out something of the causes of heart disease. The House would be taking a terrible and overwhelming responsibility if it stopped these investigations. He did not think that any Member who went round a hospital and saw the wretched and blue-faced people sitting in bed gasping for breath, their legs swollen with dropsy, would take the responsibility of stopping these experiments. He thought that when they had a report from the Medical Research Committee saying that in their opinion this Bill would be in many directions a hindrance to the work of medical research their opinion was worth the utmost respect. That Committee had been working particularly on the question of rickets, and recent events had led to a great spreading of that disease in Central Europe, where it affected 8 per cent. of the children. —The honourable Member was still speaking at 5 o'clock when, in accordance with the rules of the House, the debate stood adjourned. The Bill accordingly was "talked out."

Typhoid Fever in the Army.

Mr. ROBERT YOUNG asked the Secretary for War whether a number of cases of illness in the army occurring in 1915 and 1916 in the Near East and sent to Malta, Lemnos, and other places were diagnosed by the clinical symptoms as typhoid fever; whether the majority of these cases were subsequently returned as suffering from other diseases, the altered diagnosis being based on agglutination tests performed by bacteriologists sent out for the purpose; and if he would say how the figures regarding typhoid fever in the late war could be compared with those for other campaigns in view of this alteration in the method of diagnosis.—Mr. CHURCHILL replied: Under active service conditions in the field it was often impossible to carry out careful and prolonged bacteriological and clinical examination of cases. Under these circumstances a provisional diagnosis was returned. Such cases on reaching the base hospitals, as at Mudros, Malta, and Lemnos, were submitted to bacteriological and clinical examination as a routine measure by the pathologists and physicians attached to such hospitals. In many cases the provisional diagnosis was altered, but until the investigation of the records which is now proceeding is completed it is not possible to give any estimate of the number of cases in which such alteration of diagnosis was necessary. Some of the cases provisionally diagnosed as enteric were subsequently returned as suffering from other diseases; and other cases, provisionally diagnosed as dysentery or diarrhœa, were finally diagnosed as typhoid or paratyphoid fever on the bacteriological evidence. The diagnosis of disease has undoubtedly been more accurate in the late war than in any previous campaign.

Mr. WATERSON asked the Secretary for War whether the figures regarding typhoid fever in the British army contained in the recent White Paper were based on returns made by clinical diagnosis of the disease, or whether they were based on returns made by bacteriologists after agglutination tests had been made.—Mr. CHURCHILL replied: The figures in question were based on returns made both by clinical and bacteriological diagnosis. Bacteriological diagnosis was employed in every case so far as the circumstances permitted.

MONDAY, MARCH 22ND.

Medical Services in the Army.

On the motion for going into Committee on the Army Estimates, 1920–21, Vote A,

Lieutenant-Colonel FREMANTLE said he wished to call attention to the Army Medical Service from a higher point of view than that taken professionally. Medical administration was not merely concerned with the cure of the sick and wounded and the prevention of disease, but it went to the root of efficiency, and therefore to the efficacy of strategy. Discoveries had been made from time to time of vast wastage in the reduplication of technical personnel in different forces of the Crown. He would confine himself to the medical service. They had not only the Army Medical Corps and the Naval Medical Service, but the Flying Force was now starting a medical service of its own. There was also frequent overlapping of the ground covered by the Army Medical Corps, by the Indian Medical Service, the Colonial Office, and the Foreign Office. An enormous economy might be effected by a system of coördination, and he suggested that the Army Council should take up the question of creating an Imperial General Medical Service. The work of medical men who had seen service generally ended at the age of 45, and the country then threw them on to the rubbish-heap or the golf links. But there were abundant possibilities for these men if the Army Medical Service were linked up with the civil medical services, such as the Poor-law and Pensions. Territorial officers had always been penalised, and in the late war while the medical officer who had done some training in peace-time was paid 14*s*., the officers who had not done any pre-war training got 24*s*. He strongly urged that the Director-General of the Army Medical Service should not only have a seat on the Army Council, but should be responsible for, and have the power to guarantee, the organisation, medical and sanitary, for the care and comfort of the sick and wounded in war.

Captain ELLIOT said we had lost many thousands of men in the late war because the Army Council had not taken the straightforward advice of the Medical Service. The medical corps had made contributions of the greatest value in respect to the treating of our armies in the field. He would simply mention two instances. It was impossible to give the young recruit too much to eat. They gave these growing boys 4000 or more calories a day, and they bolted it up, and like Oliver Twist came back for more. The best proof that these recruits did not get enough to eat was the fact that they were willing to spend their own money on food. They were to be seen going to the canteen to buy rice pudding at 11 o'clock in the morning. At the time of the demobilisation the physiological experts warned the Army Council that they would have a lot of these young fellows coming back to the camps, and that it would be necessary to increase the rations. But the Army Council took no notice until the Australian troops mutinied, and then the Council conceded to force what they had hitherto refused to reason. Another case in point was in regard to a disease called bilharzia, which attacked our troops in Egypt. As a result of medical discoveries our troops were rendered practically immune from this scourge, which had existed in Egypt from the time of the Pharaohs. He strongly urged that the Director-General of Medical Services should have a seat on the Army Council. There were many medical men in Mesopotamia who were not released because they were told that they were indispensable in the teeth of the fact that there were a number of native doctors there who were able to take their place. The reason why they did not do so was because, whatever might be said about the capacity of India for self-government, there was no doubt that the ordinary Indian resented extremely having to depend upon native medical officers. Yet the white doctors were actually paid less than the native doctors. This grave injustice was causing the utmost discontent in Mesopotamia, which was spreading to the Indian Medical Service, a noble force which at present was in a state of seething unrest. As soon as these officers were given permission to resign their commissions many hundreds of them would do so. He welcomed the small estimate for starting an Army Dental Corps. Dental treatment was one of the black spots in our Medical Service. He thought it was scandalous, after what the army nursing sisters had gone through, that they should not have the direct status of an officer. The women medicals n attendance with the auxiliary forces were in an even worse state. They were not counted as belonging to His Majesty's forces at all, and they did not get the income-tax rebate to which the other branches of the Service were entitled. The attitude of the War Office towards women was distinctly archaic, and badly required revision.

Sir A. WILLIAMSON (Financial Secretary to the War Office) said that a considerable amount of coöperation existed between the medical branch of the War Office and the civil medical service, and there was every desire to extend it and make use of the best knowledge that was available wherever t could be found.

The vote was agreed to.

National Health Insurance Bill.

Dr. ADDISON (Minister of Health), in moving the second reading of the National Health Insurance Bill, said it was proposed to increase the benefits in the case of men from 10*s*. o 15*s*. a week for sickness and from 5*s*. to 7*s*. 6*d*. for disablement. In the case of women sickness benefit would be ncreased from 7*s*. 6*d*. to 12*s*., and disablement benefit on the ame lines as for men. These benefits necessitated an ncreased contribution apart from the increased Treasury ontribution of 3*d*. per insured person—namely, 2*d*. from the mployer and 1*d*. from the employee. Maternity benefit was ncreased from 30*s*. to 40*s*. Sanatorium benefit it was proposed to take out of the Insurance Act altogether as the first tage in a comprehensive policy of dealing with the whole problem of tuberculosis in respect of all sections of the population. That policy he hoped at some not too distant ate to be able to state to the House. An extra mount, roughly equivalent to 2*d*. per insured person, would be given for the employment of medical referees nd consultants whom societies had hitherto had to mploy for themselves. The actual figure which would e contributed by the combined fund towards the cost f medical benefit was 9*s*. 6*d*. He had separated the medical benefit funds into distinct and definite departments. Drugs would be quite separate from the payments to practitioners for their services. He had arranged for a specified um, in the aggregate £300,000, which would be devoted, nder proper supervision and checks, in assisting the locomotion of practitioners in rural and scattered districts. The medical men, with whom he had had many meetings, had ecognised that in many respects, in certain places, insured ersons had not had so satisfactory a service as they ought o have. The standard he had laid down, and which had een frankly accepted, was that a practitioner should give to he insured person as good and complete attendance as he ave to a private person. He was happy to say that the rbitrator had accepted the offer of 11*s*., which he had made o the practitioners.

Mr. T. MYERS said he was glad that the right honourable entleman had referred to the provision to be made for medical referees. It had always been a delicate matter for private practitioner attending panel patients to exercise hat authority which he might have done for fear of suffering injury in other directions. A limitation should be put n the number of panel patients a doctor could take on.

Mr. ORMSBY GORE criticised the proposal to continue anatorium benefit in Ireland when it was being abolished lsewhere. Tuberculosis would never be effectively comated if it was treated in one way in England and another n Ireland.

Captain ELLIOT called attention to the serious position of the hospitals. The benefits of the National Insurance would have been utterly illusory had it not been for these voluntary institutions which were now faced with ruin. Yet the Ministry of Health made no announcement of anything to be done for them. Much remained to be done for the public health of this country, but much had been done. The people of this country were the healthiest in the world. They lived longer than the people of France or the people of America. Since the Franco-German War science had added five years to the life of the people of this country, and if the Minister of Health was properly supported he could add 10 or 15 years to the lives of our people. These were the real annexations and indemnities, and the doctors were the men to get them.

Dr. ADDISON assured the House that there would be no hiatus in the treatment of tuberculosis owing to the change of policy. He thanked the Consultative Council for their aid in framing the Bill.

The Bill was read a second time.

Duplicate Artificial Limbs.

Mr. RAMSDEN asked the Pensions Minister if he would say what were his reasons for refusing to supply a duplicate set of limbs to officers and men who had been amputated above or below the knee. This attitude caused hardship to the men concerned, as artificial limbs frequently needed repairing which necessitated the men staying in bed and thereby breaking time until the limbs were repaired, when the dissatisfaction of the employer, owing to the time which was so frequently broken, acted as a deterrent to the men obtaining work.—Sir J. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: There has been no refusal such as is suggested in the question. On the contrary, the principle is fully recognised that every officer or man who has lost a limb in the war should be supplied with a duplicate artificial limb for use when the first artificial limb is in need of repair. The systematic issue of the duplicate limb was commenced in October last, when the supply of the first artificial limb to the 42,000 officers and men concerned was approaching completion, and it is making good progress.

TUESDAY, MARCH 23RD.

Inoculation in the Army.

Mr. CHARLES EDWARDS asked the Secretary for War whether between 150,000 and 200,000 uninoculated men served in the British armies in France during the war; whether less than 4000 of these suffered from enteric, typhoid, or paratyphoid fever; and whether he attributed the immunity of these uninoculated men to the precautions taken regarding the provision of pure water and food and the measures for the destruction of refuse taken by the sanitary services.—Mr. CHURCHILL replied: During 1917 there were in France approximately 30,000 men who had not recently, or had never, been inoculated, and during 1918 the number was approximately 70,000. Good sanitation has always had a beneficial effect in checking the spread of disease. It is, however, also true that the immunity these men enjoyed was due to the fact that there was only a very small proportion of non-inoculated men in each unit.

Effect of Theatre Queues on Public Health.

Sir JAMES CORY asked the Minister of Health whether his department had considered the effect on the health of the community of the practice of forming queues in all weathers for the galleries and pits of the London theatres; and whether he would consider the desirability of calling a conference of theatre and music-hall managers to consider measures for doing away with this practice.—Dr. ADDISON replied: There is no sufficient evidence of the injurious effect of theatre queues to justify me in taking action in the direction suggested by the honourable Member.

Miners' Nystagmus.

Mr. SWAN asked the Secretary for the Home Department if he would state what steps, if any, were being taken either to mitigate or prevent the spreading of the disease of miners' nystagmus; and if he was aware of the great loss of coal output to the nation caused by it, as well as the physical pain caused by the disease to those affected.—Major BAIRD (Under-Secretary to the Home Office) replied: Working in the insufficient light given by miners' lamps is recognised as the main cause of this disease, and the question of improving the illumination is being investigated by a Departmental Committee, which my right honourable friend appointed last May under the chairmanship of the present Inspector of Mines. The Committee has been taking evidence both from those engaged in the industry and from scientific and medical experts, and conducting researches at the Home Office Experimental Station at Eskmeals and elsewhere, and they are about to carry out a series of practical trials with lamps giving a better light. The serious effects of this disease are only too obvious, and the honourable Member may be assured that all possible steps are being taken to find an effective remedy.

Medical News.

UNIVERSITY OF CAMBRIDGE: DIPLOMA IN RADIOLOGY AND ELECTROLOGY.—The next examination will be held at Cambridge: Part I. on Tuesday, July 27th, with practical work, and viva voce examination on July 28th; Part II. on Thursday, July 29th, with practical work on the following day. Candidates desiring to take the diploma by thesis should apply to the secretary, Dr. Shillington Scales, Medical Schools, Cambridge, for the necessary certificate forms. Should sufficient entries be received, courses of lectures and practical work in physics and in electrology will be held in Cambridge, beginning June 22nd, and finishing about mid-August, and in radiology, beginning Oct. 12th, and finishing in time for the examination at Christmas. The necessary clinical work can be carried out at Addenbrooke's Hospital, Cambridge. The physics course will be given by Dr. Crowther, by arrangement with Professor Sir Ernest Rutherford; the courses in radiology and electrology by the same lecturers, who have given the courses in London. Application should be made to Dr. Scales. It is hoped in future, to hold courses and examinations twice a year, the courses in Cambridge alternating with those in London.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates passed in the subjects indicated:—

FINAL EXAMINATION FOR M.B. AND CH.B.

Part I., Pathology.—F. H. Alexander, G. P. F. Allen, Eleanor E. Briant, G. L. Gately, H. T. Hughes, Isobel K. Johnstone, J. G. L. Jones, R. J. Jones, H. R. Madan, J. B. Oldham, T. R. Roberton, C. F. H. Sergeant, F. C. H. Sergeant, S. S. Shrikanth, C. C. L. Spurring, and T. A. Williams.

Part II., Forensic Medicine and Toxicology and Public Health.—J. F. C. McColl, J. C. Twomey, and S. A. Walker.

Part III., Medicine, Surgery, Midwifery.—W. H. Butler and Mary S. Share-Jones.

Honours, Second Class.—Isabel M. Collier and W. H. Evans, distinction in Medicine; and H. Reid, distinction in Surgery.

DIPLOMA IN PUBLIC HEALTH.

A. E. Saunderson and W. F. Young.

LICENTIATESHIP IN DENTAL SURGERY.

Final Examination.—Dorothy A. Canning, C. H. Fearn, J. P. Flynn, G. Hepburn, E. F. Hope, A. R. B. Littlar, A. F. Morton, and J. Whitehead.

UNIVERSITY OF MANCHESTER.—At examinations just concluded the following obtained the Diploma in Public Health: Ahmed Aziz, J. P. Broom, J. H. Campain, T. E. Dickinson, W. E. Fitzgerald, J. R. Jagger, E. F. Hill, M. R. Soni, A. V. Stocks, C. F. White; and the following obtained the Diploma in Veterinary State Medicine: W. A. Macgregor, E. J. B. Sewell.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The following committee has been appointed to exercise the powers of President of King Edward's Hospital Fund for London during the absence from the United Kingdom of the Prince of Wales:—The Earl of Donoughmore, K.P., Viscount Finlay, G.C.M.G., the Governor of the Bank of England.

A COMPLIMENTARY dinner to Sir George Makins will be held on Monday, May 10th, at the Wharncliffe Rooms, Hotel Great Central, London, at 7.30 P.M. for 7.45. Sir Cuthbert Wallace will take the chair. Any of Sir George Makins's friends who would like to be present are asked, if they have not already done so, to notify Mr. C. Max Page, 134, Harley-street, London, W. 1, before April 30th, in order that seating arrangements may be made. The payment of 1 guinea, not including wine, is to be made at the Wharncliffe Rooms, and no tickets will be issued.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—At the annual meeting of this guild, held on March 19th, at the London Mansion House, under the presidency of the Lord Mayor, appeal was made on behalf of an educational fund to assist the children of the beneficiaries of the Fund and also for the endowment of a hostel in London for necessitous widows and children on the books of the guild. For the hostel fund some £8000 to £10,000 are required. Lady Barrett made the interesting suggestion that kind-hearted people might undertake to become fairy godparents to individual children, and Miss Lillian Braithwaite said that as money was being squandered so recklessly in these days the necessary funds for the hostel ought to be forthcoming in a few weeks. No charity supplies a greater need than the Royal Medical Benevolent Fund, and the Guild not only relieves distressed members of the medical profession, who in caring for the lives of others have failed to make provision for their own, but also looks after the education of their children and orphans. Lady Fripp, 19, Portland-place, London, W. 1, is now chairman of the general purposes committee.

DONATIONS AND BEQUESTS.—By will the late Lord Portman left £1000 each to the Blandford Cottage Hospital and the Royal Blind Pension Society, £500 each to the Metropolitan Convalescent Institution, the Herbert Convalescent Home, Bournemouth, and the Samaritan Hospital; £250 each to the Weymouth Eye Infirmary and the Surgical Aid Society.

THE ROLL OF HONOUR HOSPITAL FOR CHILDREN (WOMEN'S HOSPITAL FOR CHILDREN).—This hospital, which was founded in 1912 at a time when there were few infant welfare centres available and when the examination of elementary school children was impeded by the absence of any local clinics, is situated in the Harrow-road, in the centre of a district with an immense juvenile population. At present the work is being carried on in workmen's cottages provisionally adapted for the purpose, but a permanent new building is urgently needed, and while a suitable site has been obtained only £13,000 have as yet been promised or subscribed towards the building fund. The eighth annual report, dated December, 1919, states that there is always a large waiting list for admission to the wards and the out-patient attendances continually increase. The number of cases admitted to the in-patient department was 144 and the number of new cases dealt with in the out-patient department 6246, the total number of attendances being approximately 64,722. The address of the hospital is 688, Harrow-road, London, W. 10, and the bankers are the London County, Westminster, and Parr's Bank, Harrow-road.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on March 18th, with Sir Francis H. Champneys in the chair. Several midwives were struck off the roll, the following charges, amongst others, having been brought forward:—

Being in attendance at a confinement, the case being one of twins and the placenta and membranes not having been completely expelled two hours after the birth of the first child, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (3); she neglected to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution before making the first internal examination of the patient, as required by Rule E. 8 (a), and medical aid having been sought for the patient she neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a). The midwife not being scrupulously clean in every way, as required by Rule E. 2; not taking and recording the pulse and temperature of her patients at each visit, as required by Rule E. 14, not entering records of the pulse and temperature of her patients in a note-book or on a chart carefully preserved as required by Rule E. 14. Being in attendance at a confinement and the patient suffering from dangerous varicose veins with swelling and tenderness, on the day of the confinement, and continuing so to suffer, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (2). The midwife neglecting to disinfect her hands and forearms before touching the generative organs of the patient, as required by Rule E. 4, and not keeping her register of cases as required by Rule E. 24. A midwife did not give to the local supervising authority every reasonable facility to secure a proper inspection of her register of cases, her place of residence, and an investigation of her mode of practice pursuant to Rule E. 25. Being in attendance at a confinement, and the patient suffering from serious rupture of the perineum and other injuries of the soft parts, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (3). A child suffering from inflammation of and discharge from the eyes during her attendance, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5); she neglected her responsibility for the cleanliness of, and she neglected to give all necessary directions for securing the comfort of, the mother and child, as required by Rule E. 12. Two midwives were guilty of misconduct in that, being single women, they had each given birth to an illegitimate child.

An ordinary meeting of the Board was held on the following day, when there came under consideration the limit of number of cases a midwife should take in the course of a year. A letter was considered from the assistant clerk of the London County Council stating that in many cases the omissions and failures on the part of midwives to observe the rules of the Board are attributable to the fact that such midwives have undertaken more confinement cases than could be coped with, and suggesting the desirability of limiting the number of cases which a midwife should be allowed to take in the course of a year. The Board decided that in their opinion it is impossible to rule that a midwife shall not take more than a certain number of cases in the course of a year as the number of cases which can be taken without affecting the proper conduct thereof depends on factors of a varying nature, such as concentration and dispersal of cases, the normality or otherwise of the cases, the powers of endurance of the midwife, and the like. The procedure for dealing with midwives who neglect their duties is laid down by the rules of the Board, and in the opinion of the Board is sufficient for the purpose of preventing undue multiplication of cases undertaken.

University of Sheffield.—Post-graduate lectures in the Faculty of Medicine will be delivered during April, May, and June by Professor A. M. Connell and Professor A. J. Hall. The lectures will be delivered every Wednesday afternoon at 4 o'clock, and will be open to all members of the profession, free of charge.

The Osler Presentation Volumes.—The printing of the volumes that were to have been presented to the late Sir William Osler on the occasion of his seventieth birthday is at last completed. These volumes have been dispatched from America, and their arrival may be expected in a few weeks. The long delay in their appearance has been due to strikes and other disturbances in the printing and publishing trades.

Manchester Milk-supply: Improvements Suggested.—A report containing a strong indictment of the existing system of milk-supply in Manchester has been published and will be submitted to the city council next month. It recommends municipalisation of the milk distribution, and gives evidence in favour of a change in milk distribution. Contaminated milk has recently been the cause of an extensive outbreak of sore-throat in one district, of scarlet fever in another, and also of diffusion of enteric fever and diphtheria. Professor S. Delépine recently conducted an analysis of Manchester milk, and, according to the report, he found that the number of clean samples was small, and that the keeping quality of the milk was low. A large number of samples became sour after 10–14 hours' incubation at 85° F. Cow's milk, when properly collected and distributed, should remain good for over 5 hours in 80 per cent. of the cases, and for 35 hours in all cases. Of 39 samples taken from Manchester hospitals 4 per cent. contained over 1,000,000 bacteria per c.cm. Some samples from large dairies contained tubercle bacilli. If the grading system were adopted for Manchester most of Manchester's milk, so far as cleanliness is concerned, would be placed in the lowest grade. The proposal to improve matters is to buy up all the milk businesses in the city at a cost of £461,000, and to organise distribution on the following lines: 1. Establishment of county depôts. 2. Formation of city centres to which the milk could be directly consigned, and which could supply an area of convenient size. These areas would be divided into districts served by carts or dandies, and there would be only one delivery in a district. 3. Shops or dairies to be provided under skilled management, to be suitably constructed, and clean and attractive. The shops would be stocked with all kinds of dairy produce made at country depôts.

Bradford Medico-Chirurgical Society.—A meeting of this society was held at the Royal Infirmary on March 16th, and was devoted to the discussion of venereal diseases.—Dr. H. H. White read a paper entitled "A Brief Review of Venereal Diseases, with Special Reference to Modern Methods of Treatment: Some Points in Diagnosis and Some Complications." He pointed out that gonorrhœa was a most difficult disease to treat and cure. Patients rarely came early enough for it to be possible to abort it, though he had recently aborted one case with 15 per cent. argyrol twice a day for three days, followed by irrigation with potassium permanganate, and had seen other cases aborted with acriflavine. In the acute stage the best results were obtained by irrigation with potassium permanganate and sodium carbonate, prescribing an alkaline mixture and rest in bed. When the posterior urethra was affected the case was much more difficult to cure, and the prostate should then always be examined. The complications of gonorrhœa were legion, and he described them and their treatment. He also dealt with gonorrhœa in women, pointing out how difficult it was to diagnose clinically; he described its treatment and pointed out that the urethra in women was a common hiding place for the gonococcus, and that this was the chief source of conveying the disease to others. He then dealt with syphilis, and said that as soon as dark-ground illumination showed the spirochæte treatment with 606 or 914 should be given forthwith. He showed the importance of not accepting an early negative Wassermann as proof that the disease did not exist.—Dr. W. Campbell read a paper on "Matters Relating to the Diagnosis of Syphilis and to the Serological Methods used in the Control of Treatment." He pointed out the various sources of error in the Wassermann reaction, and showed sera illustrating these errors. He demonstrated the necessity of titrating antigen so as just to exclude a non-specific reaction in cases of psoriasis, and pointed out the importance of examining the blood as soon as possible after its removal from the patient to prevent the serum becoming anti-complementary. The Wassermann reaction of the cerebro-spinal fluid was also dealt with. The discussion was continued by Dr. Margaret Sharp, Dr. A. F. Martin, Dr. Hambley Rowe, Dr. J. J. Buchan, and others.

Cremation Society of England.—The annual meeting of the society will be held at the Brayton Galleries, 316, Regent-street, London, W., on Wednesday, March 31st, at 3 P.M.

Colonel Sir George Hastings, M.D., has been appointed an Esquire of the Order of the Hospital of St. John of Jerusalem of England.

Yarmouth Children's Convalescent Home.—The Yarmouth Children's Convalescent Home is by no means a purely local institution, as is evident from the fact that during last year 236 of the children admitted came from London, 91 from Norwich, 5 only from Yarmouth, and 20 from various other places. A large proportion of the children from London were sent by various branches of the Invalid Children's Aid Association, which showed its appreciation of the work of the home by contributing liberally to its support. Of the 352 cases admitted during 1919 148 were discharged cured, 178 were much improved, 17 benefited, and the condition of 3 remained unaltered. Owing to the fact that the expenditure during 1919 exceeded the income by £163 16*s*. 1*d*. the committee has reluctantly decided that in future a weekly payment must be made for each child admitted.

Freemasons Hospital for Paying Patients.—The Freemasons War Hospital is being remodelled in order to provide an institution intermediate between the charitable public hospital and the nursing home with its attendant heavy expenses. Charges are to be about £3 to £3 5*s*. per week, and the patient will feel that he is paying the amount which it would or might cost a charitable hospital to maintain him. The rest will be borne by an endowment fund. The surgeons on the visiting staff are being asked to look upon the institution in the same way as they would regard an ordinary hospital, and to take small nominal contributions towards the surgical expenses, the surgeon not being brought into contact in financial matters with his patient. The same applies to the anæsthetist. Adult patients will be given a moderate amount of privacy by semi-cubicles curtained off. The nursing staff will consist of fully trained nurses, without staff nurses and probationers. The hospital will be opened at the beginning of May in the premises formerly occupied by the Chelsea Hospital for Women, 237, Fulham-road, London, S.W. 3.

London and Counties Medical Protection Society, Ltd.—The annual general meeting of this society was held at 32, Craven-street, Strand, W.C., on March 17th, Sir John Rose Bradford, the President, being in the chair. The President having made a few introductory remarks alluding to the prosperity of the society during the past year, as shown by the large number of candidates seeking election and their geographical distribution all over the country, Mr. C. M. Fegen, treasurer and chairman of council, moved the adoption of the twenty-seventh annual report and balance-sheet. He said that the council was conscious of its responsibilities in view of the increased cost of everything—salaries, legal expenses, and those of organisation—while depreciation in the value of securities had also to be reckoned with. The net depreciation for the year was somewhere in the neighbourhood of £800, but this in no way interfered with the income of the society nor with what it was hoped would be the ultimate value of the securities, as they were all gilt-edged. The finances were really extremely good, the reserve funds had crept up during the last 20 years from £1400 to £25,500, and the first thing a medical man should do on qualification was to join one or other of the protection societies—he might be excused for thinking that they should join the London and Counties Medical Protection Society, Ltd.—in order to safeguard himself. Sir Thomas Parkinson seconded the adoption of the report, and this was agreed to unanimously.

Dr. Dennis Vinrace proposed, Dr. George Crichton seconded, and it was resolved *nem. con.*:—

> That a sum not exceeding £450 be paid each year for the remuneration of the members of the council of the society attending meetings of the council, whether ex-officio or elected (except the paid officials), at the rate of 1 guinea to each member of the council for each attendance at a council meeting; and such remuneration shall not include the sums paid as travelling expenses in accordance with the resolution passed at the annual meeting of the society on May 16th, 1917.

Sir John Rose Bradford was re-elected President of the society. The existing vice-presidents were all re-elected, with the addition of Sir Charles Gordon Watson. Mr. Fegen was re-elected treasurer of the society. The four retiring members of council were re-elected, with the addition of Dr. J. P. Hedley, to fill the vacancy created by the recent election of Dr. Pollock Muir as a vice-president. Dr. Hugh Woods and Mr. A. G. R. Foulerton were re-elected general and financial secretary respectively. Messrs. Duncan Belcher and Co. were re-elected auditors at a remuneration of 25 guineas. The meeting ended with a vote of thanks to the President.

Appointments.

BEAUMONT, G. E., D.M. Oxon., M.R.C.P., D.P.H., has been appointed Assistant Physician to the Middlesex Hospital.

GEBBIE, N., M.B., Ch.B., D.P.H., Assistant Medical Officer of Health, Ilford Urban District Council.

HOBHOUSE, E. W. N., M.B. Oxon., M.R.C.P., Physician to Out-patients, Victoria Hospital for Children, Tite-street.

SHERA, J. E. P., M.D., L.R.C.P., Medical Superintendent, Somerset and Bath Asylum.

SYMONDS, C. P., M.A., M.D. Oxon., M.R.C.P., Assistant Physician for Nervous Diseases Guy's Hospital.

Certifying Surgeons under the Factory and Workshop Acts: **WILLMOTT**, C. M., L.R.C.P. & S. Edin. (Leyland); **TYLOR**, C., M.D. Camb. (Long Melford); **MILLER**, R. (Stock); **DAVIDSON**, H. A. C., L.R.C.P. & S. Edin. (Coupar Angus); **YULE**, R. M., M.D. Aberd. (Lerwick); **GASTEEN**, H. D., L.R.C.P. & S. Irel. (Gamlingay); **ANDREWS**, J. A., M.B., B.C. Camb. (Bovey Tracey); **SEAL**, P. H., M.B., B.S. Lond. (South Molton); **HART**, J. D., M.B., Ch.B. Glasg. (North Walsham); **GILMOUR**, R. T., M.R.C.S., L.R.C.P. Lond. (Maidenhead).

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital.—Jun. H.S. £150.

Belgrave Hospital for Children, Clapham-road, S.W.—H.P. and H.S. £100 and £75 respectively.

Birkenhead Borough Hospital.—Sen. and Jun. H.S.'s. £200 and £170.

Bradford City.—Medical Woman for Ante-natal Work. £500.

Bridgend, Glamorgan County Asylum.—Jun. Asst. M.O. £350.

British Guiana.—Asst. M.O. £400.

Burnley, Victoria Hospital—H.S. £250.

Burton-on-Trent Infirmary.—H.S. £200.

Carlisle City.—Female Asst. M.O. £500.

Central London Ophthalmic Hospital, Judd-street, W.C.—H.S. £50.

Derby, Derbyshire Royal Infirmary.—Oph. H.S. £200.

Derbyshire Education Committee.—Sch. Dentist. £450.

Dorchester, Dorset County Council Education Committee.—School Dentists. £400.

Dublin, Central Midwives Board for Ireland.—Examiners in Midwifery.

Glasgow, Bellahouston Hospital.—Res. M.O. £250.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P and Asst. H.S. £175 and £150 respectively.

Gravesend Hospital.—H.S. £200.

Greenwich, Metropolitan Borough.—Asst. M.O.H. and M.O. for Tuberculosis Dispensary. £700.

Hereford County and City Mental Hospital.—Second Asst. M.O. £350.

Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. 30 guineas.

Hospital for Sick Children, Great Ormond-street, London, W.C.—Res. Med. Supt. £200. Also Asst. Cas. M.O., H.P., and H.S. £50 each.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.—S.

Huddersfield Royal Infirmary.—Assist. H.S. £150.

Italian Hospital, Queen-square, W.C.—Hon. Asst. Anæsth.

Leamington, Warwickshire and Coventry Joint Committee for Tuberculosis.—Asst. Tuberc. O. £500.

Leeds Public Dispensary.—Res. M.O. £200.

Liverpool Education Committee.—Two Asst. Sch. M.O.'s. £350.

Liverpool, Stanley Hospital.—Two H.S.'s. £150.

London Homœopathic Hospital, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Anæsth. £50. Also Asst. Surg.

Macclesfield General Infirmary. Res. H.S. £200.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Manchester Children's Hospital, Pendlebury, near Manchester.—Res. M.O. £150.

Manchester Hospital for Consumption and Diseases of the Throat and Chest, Bowdon, Cheshire.—Res. M.O. £350.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Middlesbrough, North Ormesby Hospital.—Asst. H.S. £175.

Miller General Hospital for South-East London, Greenwich-road-London, S,E.—Hon. S.

Monmouthshire County Council.—Pathol. and Bacteriol. £750. Also Female Asst. M.O. £500.

Mothers Hospital, 153-163, Lower Clapton-road, Hackney, E.—Res. M.O.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Fitzroy-square, W., and Northwood.—Two Hon. Radiologists.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Hon. Asst. P.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Hon. Gynæcologist.

Newark Hospital and Dispensary.—Res. H.S. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Anæsth.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £200.

Nottingham General Hospital.—Cas. H.S. £150.

Paddington Green Children's Hospital, London, W.—S. and P.'s. Also H.P. and H.S. £150 each.

Perth Royal Infirmary.—H.S. 6 guineas per week.

Plymouth, Borough of.—Tuberc. O. £500.

Prince of Wales's General Hospital, Tottenham, N.—H.P. and H.S. £200 each. Also Jun. H.P. and Jun. H.S. £120 each. Also Two Hon. Asst. P.'s.

Queen Mary's Hospital for East End, Stratford, E.—H.P.

Reading, Royal Berks Hospital.—H.S. £200.

Redhill, Surrey, Royal Earlswood Institution.—Asst. M.O. £400.

Wolverhampton and Staffordshire General Hospital.—H.S. £200.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Tipperary.

Births, Marriages, and Deaths.

BIRTHS.

BRUCE.—On March 22nd, at a Nursing Home, the wife of Olliver Bruce, M.R.C.S., L.R.C.P., of Cromwell-crescent, S.W., of a son.

EVANS.—On March 16th at Princes-avenue, Hull, the wife of Harry Loft Evans, M.R.C.S., of a daughter.

LOCK.—On March 18th, at Barnfield-crescent, Exeter, the wife of Norman F. Lock, F.R.C.S., of a daughter.

TAYLOR.—On March 17th, at Glenloch-road, Hampstead, to the wife of Charles Joseph Taylor, M.D., of Nuneaton—a son.

MARRIAGES.

COOPE—HUTCHINGS.—On March 20th, at Frodsham Parish Church, Robert Coope, M.D., to Rosalind Hutchings, of Hillsboro', Frodsham.

MIDDLEWEEK—CROSSLEY.—On March 22nd, at Duffield Church, Derbyshire, Frederick Francis Middleweek, L.R.C.P., L.R.C.S., late Major, R.A.M.C., to Lillie Marie, widow of Bertram J. F. Crossley, Captain, Sherwood Foresters.

VEY—WINGATE.—On March 4th, at St. Jude's, Southsea, Surgeon-Lieutenant F. Hamilton Vey, R.N., to Emily Hilda, third daughter of the late Captain G. M. Wingate and Mrs. Wingate.

DEATHS.

ELLIOTT.—On March 22nd, at Riviera, Brixham, George Blacker Elliott, L.R.C.S. & P. Irel., Major, R.A.M.C., aged 55.

EVANS.—On March 15th, suddenly, at Albion-street, Hull, Thomas Melancthon Evans, M.R.C.S., aged 82.

WRIGHT.—At Old Orchard, Sidmouth, on 23rd March, 1920, George Arthur Wright, B.A., F.R.C.S., Lieutenant-Colonel, R.A.M.C. T.F., Emeritus Professor of Surgery and late Administrator 2nd Western General Hospital, in his 69th year.

N.B —A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ARMY HYGIENE IN THE FUTURE.[1]

BY SIR JOHN GOODWIN,
DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.

AFTER explaining the organisation of the Directorate of Hygiene, which is on such a basis as easily to be expanded in the event of war, Sir John Goodwin indicated some of the main military problems of the future. These include :—

(a) *The control of physical training.*—In the services physical training has been a subject of considerable medical interest, and promises to be more so. A number of selected officers are detailed for special training in this branch of activity, and a very complete and satisfactory programme has been evolved. The aim has always been to improve individual physique by physical and recreational training, and to establish character and esprit de corps in the process. The physical training does not seek to produce muscular development in individuals, so much as active, supple, and physiologically fit men; while the importance of recreational training in its relation to physique, character, and morale cannot be overstated. Recreational training implies the participation of every individual, not the production of a few experts to be placidly watched by their inactive fellows. In the war elaborated recreational training schemes and widely competitive contests in all forms of athletics were used to counter the inevitable mental depression and physical stagnation of troops coming out of trenches or sailors condemned to wait expectantly on ships at sea. The value of dancing in this connexion is not to be slighted.

(b) *The prevention of skin affections.*—This is a question of the utmost importance. During the war there was an unnecessary wastage from pediculosis, scabies, and their various sequelæ—trench fever, pyodermia, and so forth. Not less important than improved personal hygiene is the organisation of changes of clothing, disinfection and disinfestation, of baths and laundries. A definite scheme to cover these questions is essential, and the question will in time no doubt come under the survey of the civil health authorities as well.

(c) *Spacing out in barracks and in transports* is another subject which is receiving attention stimulated by the unfortunate epidemics of cerebro-spinal fever and influenza of recent years. The army has always had enlightened views on this subject, and a fair standard (600 cubic feet per man in barracks) of space has been insisted on. The head-to-head space between individuals has been considerably increased both in barracks and hospitals overseas, and also, so far as the peculiar conditions permit, on board ships.

(d) *Improving the "domestic" conditions of troops* and of their families. Under this heading is implied the improvement of barracks and married quarters in respect of heating, lighting, ventilation, the provision of baths, and so forth, in order to render troops as comfortable as possible. Contented men are better soldiers, and the soldier is entitled to such modern civilised conveniences and sanitary devices as funds permit. His financial status, his food, clothing, and medical care have all been duly considered. In similar fashion his "home" is worthy of our best efforts.

The army is generally looked upon as consisting of men only, and the fact that the officers of the Royal Army Medical Corps are responsible for the care and welfare of the soldiers' wives and families is not generally realised.

The Immediate Aims of the Directorate of Hygiene.

These include :—

(a) *The maintenance and improvement of the sanitary instinct of the troops* and the development of the "health habit." This can be brought about in part by precept and discipline, but is essentially dependent on intensifying the educational campaign. Publicity methods are required, propaganda, cinematograph pictures and lantern demonstrations to visualise and bring home what otherwise would be merely theory; these are what we hope to achieve, and such a campaign undertaken in similar fashion in the community at large would, I believe, be all to the good. To carry out these projects in the army, it is intended at once to establish schools in commands where, under the ægis of the Deputy Assistant Director of Hygiene, the latest sanitary knowledge will be instilled as widely as possible into classes of officers, non-commissioned officers, and men of all units in the vicinity. In the United Kingdom alone there will be six of these command schools.

(b) *The improvement of the scientific knowledge of officers of the hygiene service* and of army medical officers as a whole, so that they may keep abreast of the advance of knowledge of the day. The importance of trained specialists in hygiene, in tropical medicine and parasitology, in physiology and bio-chemistry, and allied subjects has long been recognised, and the army is fortunate in having at the Royal Army Medical College in London branches which are devoted to training officers on these lines. Every officer of the Royal Army Medical Corps, apart from his initial course of instruction on military subjects on entry, is required, prior to promotion to the rank of major, to go through a nine months' course at the College, where he has, in addition to those general subjects which all officers must study, the option of selecting a special subject for intensive study both at the College and at the large hospitals throughout London. In addition to the College, however, should be mentioned the School of Entomology and the School of Hygiene, where officers have opportunities for revision courses, and, furthermore, the attachment to universities, research institutes, &c., of selected officers detailed to study certain branches of work under experts of known skill. In this way we are building up a service which will, it is hoped, include members skilled in all branches of medical and the allied sciences, and able to devote their knowledge as required to army problems.

The Relations Between the Preventive Medicine Service of the Army and of the Civil Community.

In the past the two services have been somewhat self-contained, but the war brought them together, and definitely proved the value of joint effort. The value for ultimate good of the close coöperation between the Local Government Board and the War Office in health matters during the war can hardly be over-estimated. It is almost entirely a war development, and, let us hope, one destined to remain effective in the future. Prior to the war the few fixed camps and barracks were outside the interest of the civil sanitary authorities, but this independent working along parallel but isolated lines cannot ever recur.

It is inconceivable that the lessons learned as to the value of mutual support will ever permit of anything but the closest coördination of military and civilian hygienic practice. The experience and skill brought to the army by the service therein of many of the prominent and hard-working civil hygienists has undoubtedly been of stimulating value, while one may hope that the members of the civil profession have likewise taken away some knowledge in exchange which will be of value to them and to the civil community in the future. The army is fortunate in possessing a disciplined populace and a perfected organisation which permits of action for the community as easily as for the individual. In this way military hygiene has a strong position, and has been able to arrange for more detailed application of preventive medicine than is commonly possible elsewhere. The importance of regarding disease from the preventive standpoint is one of those incalculable, though possibly unappreciated, benefits which must play a part in the nation when the temporary army doctors are once again diffused throughout the country. In the same way the importance of laboratory diagnosis and ample laboratory facilities in the army will, one may hope, lead to more intimate relationship between practitioners, clinicians, and clinical pathologists than the somewhat restricted organisation of civil laboratories now permits. Indeed, the mobility, flexibility, and number of area laboratories in the army suggests the idea that possibly a similar system would be of value to the community as a whole. It is pleasing to note that liaison between the scientific workers of the army and the nation is as close at present as ever it was during the war. Our laboratories, for instance, are in many cases making examinations, vaccines, &c., for local health authorities and for hospitals which may be without adequate facilities, and are coöperating in the production of great quantities of influenza vaccine for the Ministry of Health. Such inter-relationship must be continued in the future.

Some Common Problems Affecting Both Services.

(1) *The hygiene of ports and ships* is a question of international importance which has been placed on a sound basis by the International Sanitary Convention recently held in Paris. The outbreaks of influenza on transports and the question of the hygiene of ships at sea are subjects for further study and coördinated action between port health officers, military embarkation staffs, and the shipping authorities generally.

(2) *The control of infectious disease* remains one of the primary functions of hygienists. Internotification between the army and the civil authorities must be continued and stardardised action in respect of troops on leave in infected areas or the control of the movements of infected troops decided on. How far the military system of pooling cases

---

[1] Being an abstract of the last of three Chadwick lectures on Military Hygiene in Peace and War, delivered on March 22nd, 1920. The first and second lectures appeared in THE LANCET of March 13th and 20th respectively.

of similar type and economising hospital accommodation is applicable to the decentralised civil system is uncertain, but recent agitation in respect of the lack of hospital beds suggests consideration of the question.

(3) *Housing.*—The common aim is to provide homes with the healthiest environment, ventilation, lighting, warming, &c., and the associated questions of latrines and baths. Undoubtedly there is room almost everywhere for improvement under these headings.

(4) *Maternity and child welfare.*—This, again, is a national question of the first importance, and one which is now also receiving consideration by the army authorities. In this connexion, too, must be mentioned the importance of antenatal treatment of venereal disease. There would appear no reason to doubt that an intensive effort would effect an enormous diminution of specific infection.

(5) *Research* in all sanitary problems must be continued. Even now the treatment of water, or of sewage, the methods and practice of disinfection, and so forth, are all amenable to improvement economically, if not in actual results. It is interesting to note the gradual development of the process of chlorination of water-supplies in large communities, in view of its standardisation in army practice.

(6) *The maintenance of the liaison* is dependent in part on the close relations between the Army Directorates of Hygiene and Pathology and the Ministry of Health; on the Hygiene Advisory Committee of the army, which contains members of the highest standing in the civil community; and on the various assistant directors of hygiene of commands keeping in close touch with the medical officers of health in their areas.

So that in summing up my views I would say that, in my opinion, the future prosperity and success of our nation depends to an incalculable extent on the improvement of the physical and mental standard of all members of the community; it must not merely be—as I am afraid it has been to a considerable extent in the past—a case of "survival of the fittest," but rather a perfection of every method by which mortality may be decreased, by which the production of unfits may be diminished, and by which the standard of fitness as regards man, woman, and child may be raised.

COLONIAL HEALTH REPORTS.

Cyprus.

ACCORDING to a report recently presented to Parliament on the Blue-book for 1918–19, the estimated population of Cyprus is now 306,997. In 1918 the birth-rate was 31·3 per 1000, and the death-rate 26·1 per 1000, as compared with rates of 27·9 and 18·8 respectively in 1917. The death-rate per 1000 of children under 1 year of age was 149·4 per 1000 in 1918, as compared with 124·0 in the previous year. The increased death-rate is attributable to some extent to an influenza epidemic which occurred towards the end of the year, but it is still somewhat difficult to obtain accurate information as to the causes of death and consequently to account for variations in the death-rates. Apart from the influenza epidemic there was no outbreak of serious infectious or contagious disease, and the public health and general sanitary condition of the island have been satisfactory. The colony again enjoyed complete immunity from plague, cholera, and typhus, although these diseases prevailed in the neighbouring countries.

The antimalarial campaign, which was commenced in 1913, has been carried out on the lines laid down in the report by Colonel Sir Ronald Ross, K.C.B., F.R.S., who visited the island in that year. The malarial incidence has fallen steadily from 10,035 cases in 1912 to 2414 in 1918. The spleen census shows a decrease from 17·2 per cent. in 1913 to 5·1 per cent. in 1918, and this may be taken as a most satisfactory index of the success of the antimalarial campaign.

During the year 1127 patients were admitted and received treatment in the wards of the Nicosia General Hospital, an increase of 51 on the previous year's total. The death-rate was 6·1 per cent., as compared with 5·6 per cent. in 1917. The work in the maternity wards continues to be very satisfactory. The training of native midwives is an important part of the work carried out in this branch of the institution, and 6 of these were trained and granted certificates during the year, bringing the total number trained since the wards were opened to 33. The out-patients' department was again well attended, affording relief to 8038 cases. To the district hospitals of Larnaca, Limassol, Famagusta, Paphos, and Kyrenia 2004 patients were admitted, as against 1444 in the previous year. In addition, 12,601 persons were treated at the out-patients' department. 14,515 patients also received relief during the year at the Government rural dispensaries. There were only 4 admissions to the leper farm during the year, and 7 deaths occurred. The number of inmates at the close of the year was 79, which is the lowest on record. The beneficial effects of segregation are now being experienced. Two births occurred among the inmates during the year, bringing up the number of children in the home set apart for the offspring of lepers to 11; all of them remained free from the disease. One boy who had reached the age of 18, being free from all signs of disease, was discharged from the home.

Falkland Islands.

The official report for 1918 gives the estimated population as 3252 (2270 males and 982 females), being 43 to the square mile. The birth-rate for the year was 18·13, and the death-rate 6·15 per 1000. The health of the colony has continued to be uniformly good. The climate is healthy but rigorous. To those indisposed to pulmonary or bronchial affections the weather conditions, though seldom pleasant, are at least innocuous. High winds blow almost constantly by day throughout the year, and to this may be attributed the almost entire absence of trees in the islands. There is, however, no scarcity of sunshine, compared with that experienced in the United Kingdom, and were the cold winds less continuous and trying there would be many days when the weather might almost be described as "hot." The difference between one extreme of temperature and the other is not considerable, the thermometer registering between 30 and 50° F. in winter and between 40° and 65 in summer. The rainfall in Stanley for the past few years has averaged about 27 in. per annum; rain fell on 234 days in 1917, and on 240 in 1918.

HEALTH IN BENGAL JAILS, 1918.

THE average number of prisoners daily accommodated in the jails of Bengal Presidency in 1918 was 16,761, of whom 216 were females. The total number received during the year was 83,207, of whom 1941 were females. The number of admissions was less than in 1917, but the average daily strength was increased by 832. This increase has been going on for several years, and has led to overcrowding. Of the convicts admitted 59·5 per cent. were Mohammedans and 35·8 Hindus.

Elementary Training of Juvenile Prisoners.

Most excellent work is carried out in the Juvenile Jail at Alipore, where there was a daily average of 200 boy prisoners, the number received during the year being 398 convicts and 104 under-trial detentions. At the end of 1917 a school was started for the physical and moral training of the inmates. They are taught reading and writing in elementary English and Bengali for the Bengalis, and in Hindi and Urdu for the up-country boys, with simple arithmetic and freehand drawing. About 95 per cent. of the boys admitted are illiterate, but they learn willingly and get on well. They go through a course of gymnastics and physical drill, and play football. "More than half the population gained weight, and almost all were cheerful, happy, and looked smart." Attention is also paid to their moral and religious instruction. The number of offences diminished: only 29 needed "major punishment," and no corporal punishment at all was required throughout the year.

An after-care association has been formed in Calcutta to assist discharged prisoners. Sir Walter Buchanan, K.C.I.E., Inspector-General of Prisons, who presents this report, refers to the efficient carrying out of the changes, and inauguration of a system of education for the youthful inhabitants by Major M. Galvin, I.M.S., and mentions the excellent work of the jailer, Babu A. K. Chaudhury, who takes a fatherly interest in the boys and their future welfare. They are employed in various industries likely to be useful to them on their discharge, such as printing, carpentering, weaving, &c. But the most important is the manufacture of quinine tablets. On an average 65 boys were employed at a time, and during the year 15,643 lb. of quinine sulphate were made up ready for use. This industry and other manufactures (carpentry, book-binding, &c.) resulted in a profit of 113,159 rupees. The average earning per head for the year was 572 rupees, or 47 rupees per month. At the Presidency jail there is a jute mill and a workshop where furniture, iron bedsteads, cooking ranges, &c., are manufactured, which resulted in a profit of 50,000 rupees. At Rajshahi jail the profit on manufactured articles was 89,000 rupees. In all jails prisoners are employed at their own trades or taught a useful calling of one sort or another, so that on discharge they can make a fresh start.

In regard to dietary, the use of wheat at one meal in place of rice has grown more popular. In comparison with prisoners taking rice at both meals it was found that with rice-eaters (on the habitual Bengali diet) 51·56 per cent. gained and 23·10 lost weight, while 25·90 per cent. suffered from bowel complaint. With the mixed diet 56·36 per cent. gained and 20·84 lost weight, and only 18·13 per cent. suffered from bowel complaint.

Ratios of Admissions to Hospital.

The admissions to hospital in the various jails in Bengal were at the average rate of 1462·7 per 1000, the average daily sick 57·4 and the deaths 21·3 per 1000; these ratios are all higher than those of recent years, chiefly due to influenza and consequent respiratory affections. Only 24 cases of cholera occurred, with 9 deaths; 10 of the cases were admitted at Khulna, ascribed to arrival of infected prisoners from Satkhira subjail, which was in an insanitary condition. Influenza caused 3426 admissions, of which 2675 were in July and August. The total deaths (including those from influenza-pneumonia) were only 53. Tuberculosis caused 205 admissions to hospital and 54 deaths, an increase on the figures of 1917 (169 and 37), due to influenza. Malaria caused 5172 admissions and 19 deaths (368·4 and 1·3 per 1000), almost the same as in 1917 (5127 and 19). At Chittagong jail, with an average strength of 200 prisoners, not a single death occurred. Out of the whole number of 32,249 convicts discharged during 1918, only 23·0 per cent. lost weight, while 52·91 per cent. actually gained weight, and 24·09 per cent. neither lost nor gained. This is unimpeachable testimony to the excellence of the organisation and administration of the jails in Bengal, as well as of their general sanitary condition.

In the concluding paragraphs of his report, Sir Walter Buchanan, now on the eve of his retirement, testifies to the good work done by various subordinates, and records his opinion that a majority of sub-assistant surgeons should serve for some stated period (say five or seven years) in a jail hospital, and after this that they should be employed in other branches of the Civil Medical Department and *not* revert to the Jail Department.

EONISM.

THIS name was given by Mr. Havelock Ellis in 1913 to a form of sexual anomaly characterised by the subjects taking pleasure in behaving and dressing like the opposite sex without being sexually inverted. The term, which is comparable to that of sadism or masochism, was suggested by the well-known case of the Chevalier d'Eon. In a recent paper (*Medical Review of Reviews*, January, 1920) on the subject Mr. Havelock Ellis points out that eonism denotes more than transvestism or cross-dressing, a term introduced by Magnus Hirschfeld, of Berlin, in his description of persons who took pleasure in assuming the attributes of the opposite sex and yet were not sexual inverts and seldom tended to become inverted. The phenomenon is one of erotic empathy, to use Titchener's term, derived from admiration and affection for the opposite sex without the subject being tempted to carry the inner imitation so far as to imitate the sexual desires of the opposite sex, and so to become homosexual. A description is given of a typical case in a successful author, aged 50, who presented many qualities not found in other forms of sexual anomaly—namely, moral superiority, feebleness of the sexual impulse, and a high degree of refinement, sensitiveness, and intelligence. Mr. Havelock Ellis suggests that the real physical basis for eonism, and the related psychical peculiarities, may be some unusual balance in the endocrine system inborn, and sometimes perhaps inherited, though of a slighter degree than that present in eunuchoidism or pseudo-hermaphroiditism, which has been found associated with disturbance of the hypophysis and adrenals respectively.

NATIVE NURSES IN SOUTH AFRICA.

THE influenza epidemic of 18 months ago brought home to the public of South Africa the great need for trained native women nurses to tend their own people. A scheme has been started on the Rand for the training of native women as nurses on the same lines as Europeans. Subjected to much criticism, the scheme has so far proved a success. The originator of it is Dr. Loesser, of the Central Hospital, Crown Mines. On Feb. 28th five native female nurses were presented with certificates of competence. The girls are put through a three years' course, during which they pass examinations at intervals in order to obtain the final certificate. The only difficulty that prevents native nurses perfecting their training is the specialised nature of their experience. Some mine hospitals provide much the same class of patients as military hospitals. But it is hoped that in the future certificated nurses from the mine hospitals may be given an additional course of nursing in the Native Women's Hospital in Johannesburg now being organised. It is emphasised by the organisers of the scheme that these trained native nurses will be of great value in their own territories. It is to be remembered that they are engaged solely in nursing people of their own race, and that they are under the superintendence of Europeans. It is encouraging to note that those responsible remark on the intelligence and adaptability of native girls as nurses, and the future progress of the movement will be watched with interest.

THE METROPOLITAN WATER-SUPPLY DURING OCTOBER, NOVEMBER, AND DECEMBER, 1919.

THERE is an interesting contrast in regard to rainfall in the last three returns issued by the Ministry of Health on the condition of the metropolitan water-supply. October and November were quite dry months, the mean rainfall for the former being 1·28 inches, which is 1·97 of an inch below the average mean rainfall for that month during the previous 36 years, while the figures for the latter month showed 1·79 inches, which is 0·91 below the average over the same period. On the other hand, in December the mean rainfall was 5·00 inches, being 2·02 inches above the average of 36 years. The relation of these facts to the quality of the supply is shown in the following particulars. In October the raw river waters improved in quality according to chemical tests, and the filtered waters showed a similar improvement. Compared with the averages for 1918 both raw and filtered waters showed an advance in purity. Consistent with these results there were found fewer bacteria in the raw waters, and the filtered waters were good. In November the results of the chemical examination of the raw river waters showed deterioration, as did also some of the filtered waters. Both waters, however, showed better results chemically and bacteriologically compared with the waters taken in the corresponding period of 1918. With the increased rainfall of December the raw river waters showed a deterioration in chemical quality. The filtered waters followed suit, and both raw and filtered waters were below the standard of chemical purity of 1918. Bacteriologically, however, the waters from both sources, raw and filtered, contained fewer bacteria than those samples collected in the same period in 1918. These variations are of interest in relation to the volume of flow measured at the weirs, which is, of course, dependent upon rainfall.

UNSAFE STREETS.

THE need for the Safety First campaign is clearly shown by the Government return, just issued, of the street accidents in England and Wales. The year 1919 has a sinister precedence over 1918, the figures being 33,456 and 45,544 respectively. The mechanically propelled vehicle—in other words, reckless motor driving—was responsible for 1741 of the 2239 fatal accidents, an increase of 25 per cent. over the 1918 figure. Horse-drawn vehicles were responsible for 356 deaths, as compared with 382 in 1918. The deaths from "push-bike" accidents numbered 142, as against 105 in the previous year. In the Metropolitan Police district there were 19,685 accidents, of which the City of London contributed 727. Some accidents there must needs be—cautious pedestrians sometimes collide with each other—but a large part of this huge toll of life and limb is plainly avoidable and should be avoided.

A HIGHER STANDARD OF DYING.

THE post-bellum cry for a higher standard of living has evidently penetrated now to the South African native. At any rate he is agitating for a higher standard of burial. Trouble is reported from Germiston, a Rand mining town, on the occasion of the funeral of three natives killed while cleaning out a municipal tank. The natives were, according to the municipal regulations, to be buried without coffins. 200 of their fellow workers strongly objected, however, to their being so interred; the funeral was thereupon held up until coffins were obtained.

DEVASTATION AND DISEASE IN POLAND.

THE Friends' Unit in Poland, having succeeded in stamping out typhus in the town of Zawiercie, is looking further afield. A committee of investigation reported on March 1st the results of their inquiries. They found the villages in the valley of the Bug very largely destroyed by the severe fighting which has passed through the streets. Typhus is rampant. Lieutenant-Colonel Dunbar, who had been through the district, told them that there was much illness and very few doctors. His last report of Hrubieszow and district included 27 cases of typhus and 4 deaths during the week. Hrubieszow is "a small, rather dirty town of about 5000 to 10,000 inhabitants." Dr. Jan Opienski, the medical officer of health, they found to be pessimistic, especially since previous appeals for help to various missions had met with no response. In one village (Miemany), in the department of Hrubieszow, practically all the houses had been destroyed and the people were living in dug-outs. In many other villages the housing accommodation was reduced to a tithe of its pre-war value. The investigating committee find medical help, both in personnel and of material, to be one of the greatest needs of this district. Other necessities include housing materials, farm implements and stock, as well as food to last until the next harvest.

A BOOK ON TREES.

THE scientific study of the tree has been somewhat neglected, and any serious contribution to the subject is, therefore, to be commended. Mrs. M. Grieve, F.R.H.S., a pioneer in the movement for cultivating in this country medicinal herbs, hitherto obtained from abroad, and principal of the Whins Medicinal Herb School and Farm, Chalfont St. Peter, Bucks, has published a timely little book entitled, "Economic Trees and Their By-Products." It is described as giving "a concise account of over 70 species of trees that readily grow in Great Britain, and which possess valuable by-products, now either neglected or entirely wasted." Different parts of the trees mentioned may be used for drugs, chemicals, and timber. In THE LANCET of Oct. 11th, 1919 (p. 655) we pointed out when referring to a new school of botany that there is still much to be discovered in the medicinal uses of the vegetable kingdom. Mrs. Grieve indicates here what might be accomplished even with the knowledge we already possess. Our indigenous and exotic trees afford a wealth of material for use in pharmacy, and in industrial processes. Further research may show that some of the drugs which we import may be supplied by home-grown trees, and the author is now engaged in growing the *Rhamnus purshianus*, or Californian buckthorn (cascara sagrada), from seed with hope of commercial success. Apart from the economic value of this book, the information which it contains will be welcomed by the student of botany and the lover of trees.

Fibula (L.R.C.P., &c.) would be grateful for any suggestions in a bad case of tinnitus aurium. F., married, age 40. Lasted six months; gradually getting worse. Seen several specialists; no relief. Threatened with nervous breakdown; almost on verge of suicide. Tried many of usual remedies without any success.

Mock's

RECENTLY ISSUED

Industrial Medicine and Surgery

Human health maintenance, conserving man-power, reclaiming and retraining the disabled from war and from industry—that, in a word, is the purpose of Colonel Mock's book.

It embraces such problems as prevention of occupational and other diseases, the practical application of the Safety First movement, plant and home sanitation, health supervision and insurance, first aid for the injured and diseased, plant dispensary work, reclaiming the disabled.

The field covered is *an absolutely new specialty* in medicine, having only developed during the past ten years, and particularly since the World War. The work is based on Colonel Mock's experience as chief surgeon to a large industrial institution, and on the experience gained while serving in the Reconstruction Department of the U.S. Army. The book makes a strong appeal to every physician, particularly those interested in industrial health work and the rehabilitation of the disabled of industry as well as of war. It will serve as a text-book in courses in industrial medicine and surgery in medical schools; as a reference work for employers, labor leaders, social workers, and those engaged in the new economic and social health problems of to-day. A timely feature is that on the physical examination of applicants for work. Colonel Mock's methods have the approval of the American Federation of Labor.

By COLONEL HARRY E. MOCK, M.D., Assistant Professor of Industrial Medicine and Surgery, Rush Medical College, Chicago. Octavo of 848 pages, illustrated. Cloth, 42s. net.

Pharmacology

A MANUAL OF PHARMACOLOGY - LABORATORY GUIDE IN PHARMACOLOGY - By TORALD SOLLMANN, M.D., Professor of Pharmacology and Materia Medica, Western Reserve University.

Beldam

All-British Tyres

For Grip and Long Mileage

THE principle which governs the Beldam V design of tyre achieves the following results:

1. Prevention of punctures and skidding by the flexible Vs.
2. Resiliency and speed because the tread is deep and narrow.
3. Long life, as the rubber is thickest where the wear is greatest.

DOLS' FLANNEL

DOLS' FLANNEL was the invention of a European chemist and of the Managing Director of Dols, Ltd., Huddersfield, England, prior to the great European War. Experiments have been conducted for a number of years, and the preparation has now been perfected and can be offered to the Medical Profession as most useful in the treatment of cases of—

RHEUMATISM GOUT LUMBAGO SCIATICA CRAMP
STIFF JOINTS SORE THROAT CHEST TROUBLES

and like conditions.

DOLS' FLANNEL is ready for use, as it is dry, and will last a considerable time. It can be obtained in the form of bandages, &c., or in bulk, and can be made up by the Manufacturers in any form required by the Medical Profession.

DOLS' FLANNEL is sold at fixed prices, and can be obtained from

Messrs. HARRODS, Ltd., Drug Dept., BROMPTON ROAD, LONDON, S.W. 1.

Who will supply a Special Booklet relating to the uses of the Flannel, and who have the sole selling rights in London until the end of April.

Chronic Invalidism is a very frequent sequel of Influenza.

Fellows' Syrup of the Hypophosphites

supplies the indispensable mineral salts required by the system together with the two potent dynamic agents, strychnine and quinine. It accelerates convalescence and restores strength and vigor

GLYPHOCAL (REGD.)

SYR. GLYCEROPHOSPHATIS COMP. (SQUIRE).

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

GLYPHOCAL is invaluable in **NEURASTHENIA** and in neurotic conditions. Immediate and striking improvement follows its exhibition. It is specially valuable in nervous affections accompanied by gastric weakness. As it is very palatable it does not distress even the most delicate stomach.

GLYPHOCAL WITH STRYCHNINE

Contains $\frac{1}{120}$ grain of Strychnine in each fluid drachm.

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

Strikingly successful in the **CONVALESCENCE** after **INFLUENZA.**

GLYPHOCAL WITH FORMATES

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

GLYPHOCAL with **FORMATES** acts as a tonic to both the nervous and muscular systems, supplementing the valuable tonic properties of the **GLYCEROPHOSPHATES** with those of the **FORMATES.**

STOVAINE

THE LEAST TOXIC OF LOCAL ANÆSTHETICS

USED IN THE SAME WAY AND AS EFFICACIOUS AS COCAINE

Does not create a habit and does not give rise to headaches, nausea, vertigo or syncope. :: :: *Literature on demand.*

NO HOME OFFICE LICENSE REQUIRED

Cheaper than Novocain and Benzocain and obtainable promptly in practically unlimited quantities from the manufacturers :

LES ETABLISSEMENTS POULENC FRERES

92, RUE VIEILLE DU TEMPLE, PARIS.

EVATMINE

is a reliable and extensively prescribed product which is of exceptional value in the treatment of

ASTHMA.

It secures prolonged relief and natural breathing in Asthmatical attacks, however severe, in five minutes or less, usually after one hypodermic injection, and, in addition, it definitely retards succeeding paroxysms. It is also successfully employed as a prophylactic. Small quantities of Pituitary Extract and Adrenin Solution are included in its composition. There are no contra-indications and no adverse reactions.

A recent report reads:

> "I have been treating a very intractable case of Asthma with your preparation 'Evatmine.' The patient had been a severe sufferer for years, and the case had refused to respond to every other method of treatment. The patient obtained instant and complete relief and a good night's rest after the first injection. Two other injections gave the same excellent result. It is six months since she had the last injection, during which time she has not had a single attack of Asthma. Such a result is indeed remarkable."

"PEPTENZYME"

In Gastric Catarrh, Chronic Dyspepsia, and Constipation.

Contains the nucleo-enzymes of the salivary, peptic, and intestinal glands, and also the nucleo-enzymes of the pancreas and spleen. **PEPTENZYME** thus differs from other digestive agents and comes nearer the true digestive secretion than anything else.

We know that the flabby muscle only grows strong by use, and the stomach cannot be aided by having its work done for it. Extensive work in Physiology shows us that the digestive glands adapt their secretion to the character of the food taken in, and what we term indigestion is the inability of the gland to give forth the proper secretion, and this secretion is supplied by the granules which are found in the protoplasm of the cells. The nucleo-enzymes contain these granules in such a form that they are readily taken up by the cells and changed into the proper secretion.

The action of pepsin is only upon the albuminoid matter and simply tides over an emergency; **PEPTENZYME** not only acts in the emergency, but also feeds the glands with those products which are immediately necessary for them to take up and convert into proper ferments.

Bottles of 110 Tablets, and Elixir in 8-oz. and 16-oz. Bottles. Powder 1¼-oz.

SCIENTIFIC NUTRITION

V.

HAPHAZARD FEEDING

VITMAR

THE NEW VITALISING FOOD

has been proved by exhaustive biological tests to contain

Vitamine, Fat-Soluble A, *Growth Promoting.*
Vitamine, Water-Soluble B, *Antineuritic.*
Vitamine, Water-Soluble C, *Antiscorbutic.*

VITMAR represents a great advance in the science of dietetics and the supersession of hit-or-miss methods of invalid feeding.

VITMAR is invaluable to the doctor in the treatment of backward and delicate children. It contains a high proportion of vitamine-containing fat, rendered easily digestible by complete emulsification. An eggspoonful after meals every day. The flavour is pleasant ; children take it with avidity.

MANUFACTURED ONLY BY

CALLARD & CO. (Food Specialists),

SAPON SOAPS.

By an Eminent M.D.

THE invention of Sapon Soap is one of the greatest triumphs of applied science in modern times. Its introduction represents a revolution in the soap-making process, the ultimate effects of which are likely to be far-reaching.

1. In its Genesis and Chemistry "SAPON" Soap is radically different from all other soaps, while from a practical point of view it possesses many special advantages.

Ordinary soap is formed by the interaction of alkaline bases with organic fatty acids so as to form organic bodies analogous to the "Salts" of Inorganic Chemistry. This combination constitutes the basis of ordinary soap.

In "SAPON" Soap the alkaline bases are combined, not with fatty acids derived for the most part from the animal kingdom, but with substances from selected vegetable material

The fact that such a combination can act as a soap is a discovery of great importance, because it is obvious that soap need no longer depend for its production on the procuring of expensive fats, but can be made from the very much less expensive and more prevalent vegetable products, such as maize, linseed meal, and other starch-like substances.

The first great advantage of SAPON Soap therefore is the abundance and cheapness of the raw materials from which it can be produced—an all-important matter in these days of scarcity.

2. When ordinary soap is used in ordinary water a considerable proportion of the soap is precipitated as an insoluble compound of the fatty acid radicle with the calcium of the water. This portion of the soap is thus used up and put out of action without doing any useful work. No such waste occurs with SAPON Soaps, for the protein-carbohydrate radicles which form its organic portion are not precipitated in the form of a calcium compound.

If it be called to mind that 1000 gallons of water are able to precipitate 12 to 15 pounds of soap, the saving of the latter by using SAPON Soap will be appreciated, for in the case of large cities it would amount to tons of soap saved every day.

3. The activity and cleansing power of a soap may be regarded as depending upon :—

(1) Physical action.
(2) Chemical action.

In both these forms of activity SAPON Soaps would appear to excel ordinary soaps.

The organic radicles in SAPON Soap constitute very weak acids which are easily displaced by the stronger acids which are likely to be met with in washing. A chemical action is thus added to the physical action, and the efficiency of the cleansing power is thereby increased.

4. These theoretical and laboratory results are supported and confirmed by actual practical experience.

5. It is obvious that the value of any substance claiming to be a cleansing agent cannot be finally decided without a very great deal of attention being devoted to a consideration of its action upon the human body.

With the object of arriving at a conclusion upon this point the following experiments were carried out :—

(1) Different strengths of SAPON Soap and ordinary curd soap were applied to delicate tissues, such as the conjunctiva.

(2) Portions of the skin were kept for long periods in more or less constant contact with these solutions either by the application of compresses or by frequent washings with the liquids.

(3) The effects of SAPON Soap were noted upon tender and inflamed skins.

(4) Solutions of SAPON Soap were used as dressings for eczema and other allied skin conditions.

In the case of No. 1 method it was usually found that the ordinary person's eye will tolerate a solution of SAPON Soap from 10 to 100 times more concentrated than that of ordinary curd soap.

In the case of the second method of testing, SAPON Soap appeared to be decidedly less irritating to the skin than ordinary soap solutions of similar strength.

Method No. 3 gave similar results, while certain cases of skin lesions appeared to be definitely benefited by the use of SAPON Soap.

The last-named effects were particularly noticeable in the case of skins which were abnormally greasy. In such cases the grease was speedily removed and the complexion thus cleared and freshened.

The beneficial effects of SAPON Soap on the skin would appear to be due to several causes. In the first place, because of the chemical properties referred to above, SAPON Soap is able, owing to the ease with which its parts can be dissociated by weak acids, to combine more easily and more intimately with the fatty materials exuded by the skin, and thus ensure the more thorough removal of these bodies. In this manner the pores of the skin are kept free, and healthy action thus promoted.

It is also certainly to the advantage of the skin that SAPON Soap does *not* give rise to an insoluble lime compound precipitate, which is rough and irritating to the skin and is also liable to settle down on the epidermis and form an impermeable layer which interferes with healthy excretory action.

Again, skin diseases like other diseases cannot be regarded as primarily due to the action of bacteria alone. The skin, like all other living tissues, is very well able to look after itself and can effectually deal with the invasions of microbes as long as its own health and tone is unimpaired. It is therefore evident that the good results which have followed the use of SAPON Soap in skin infections is due to the simple fact that owing to its bland qualities SAPON Soap has cleaned the lesion without irritating it, or lowering the tone and health of the tissues, which have thus been able to recover their health sufficiently to wage a winning battle with the bacteria.

¶ A free sample will be sent to any *Member of the Medical Profession in the United Kingdom.*

Patentees and Manufacturers: SAPON SOAPS LIMITED, SAPON HOUSE, LONDON BRIDGE, E.C. 4.

Glykeron and Glyco-Heroin

ARE SYNONYMOUS APPELLATIONS AND ARE NOW KNOWN AS SUCH TO ALL DISPENSING PHARMACISTS

THESE designations may now be used interchangeably by the physician when prescribing the preparation originally known only as Glyco-Heroin (Smith).

As a safeguard against having worthless imitations of the preparation dispensed, it is suggested that the physician use the name

GLYKERON

which is non-descriptive and more distinctive, when prescribing GLYCO-HEROIN (SMITH) for **Cough, Asthma, Phthisis, Pneumonia, Bronchitis, Laryngitis, Whooping-Cough, and kindred affections of the respiratory system.**

DOSE—The adult dose is one teaspoonful every two hours or at longer intervals as the individual case requires.

For children of ten years or more, the dose is from one-quarter to one-half teaspoonful; for children of three years or more, five to ten drops.

The composition of GLYCO-HEROIN (SMITH) has not been modified in the slightest degree.

COLLOSOLS

THE ORIGINAL COLLOIDAL PREPARATIONS FOR MEDICINAL USE.

COLLOSOLS are pure and stable colloidal solutions, isotonic and isomorphic with the elements of the body.

COLLOSOLS are tested by ultramicroscopic, bacteriological, and clinical experiment.

COLLOSOL SULPHUR

This Collosol is of proved therapeutic value in Fibrositis, Arthritis Deformans, Neuritis, and in diseases of the skin such as Generalized Dermatitis, Acute Psoriasis, Acne, and Seborrhœa.

It is prepared in five different forms—for external use and bath medication, for internal administration, for injection, and as a cream, with which the affected part is gently massaged. Also as an oil for the scalp.

COLLOSOL IODINE

This Collosol consists of Iodine in its most active form, and yet non-toxic and non-staining. It never causes nausea and rarely sets up iodism.

For its efficacy in parasitic affections—see *British Medical Journal*, May 12th, 1917, p. 617.

COLLOSOL IODINE OIL. For Chilblains, Ulcerations, &c. Does not stain the skin. In boiling water as an inhalation for tonsilitis and bronchial catarrh.

COLLOSOL MANGANESE

For the treatment of Boils, Carbuncles, and other Coccic Infections.

Also for the treatment of Anæmia (see *British Medical Journal*, August 2nd, 1919, pp. 135-6).

COLLOSOL ARGENTUM

It is specially indicated in superficial bacterial infections such as **Gonorrhœa, Cystitis, Infective Wounds, and Diseases of Eye, Ear, and Mouth.** Also by internal administration in intestinal affections.

COLLOSOL QUININE

In the colloidal form quinine exists as the pure alkaloid, and the liquid is faintly alkaline. When injected, either intravenously or intramuscularly, no precipitation occurs, consequently there is no interference with the normal conditions of the blood, and rapid and even diffusion takes place. Similarly, when administered orally, absorption is even and gradual, and little interference with normal conditions takes place. Dizziness, headache, and other disagreeable effects of quinine are to a large extent avoided.

The minute particles of Collosol Quinine are compatible with either acid or alkaline media, but the ideal time for oral administration is before a meal, when the stomach is not acid.

ALSO RECOMMENDED AS A SPRAY FOR NOSE AND THROAT.

CORYTONS.

Prescribed by the Medical Profession for 35 years.

The MEDICAL PRESS & CIRCULAR (Lon. Eng.) says : " Few modern improvements in pharmacy have done so much as Benger's preparations to assist the physician in his treatment of the sick."

Benger's Food has been widely used by the Medical Profession for treating—

Diseases of the Stomach and Intestines,	**Anaemia,**
Diseases of the Blood,	**Fevers, and other Infectious Diseases,**
Tuberculosis,	**After Operations,**

and in conditions of Anorexia, Malnutrition, Gastritis, Enteritis, Appendicitis, and in Convalescence generally.

BENGER'S FOOD

for INFANTS, INVALIDS, AND AGED PERSONS,

may be prescribed to give the patient more or less digestive work as the condition indicates. It differs in this respect from preparations where the digestion is complete (predigested foods) and all other foods.

The composition of prepared Benger's Food is variable with the amount used, proportion of milk, or milk and water, upper milk, cream, etc., added, *and the extent of time it stands for self-digestion.* Formulæ and full particulars will be sent to the medical profession post free on application.

BENGER'S FOOD is sold throughout the World by Chemists, &c., in sealed tins.

BENGER'S Food

BENGER'S FOOD LTD., MANCHESTER, Eng.
Branch Offices:——NEW YORK (U.S.A.) 92, WILLIAM STREET.
SYDNEY (N.S.W.) 117, PITT STREET.
Canadian Agents: National Drug & Chemical Co., Ltd., 34, Gabriel Street,
MONTREAL, and depôts throughout Canada.

N.B.—BENGER'S FOOD is the direct outcome of the pioneer work on digestive ferments, by the late Sir William Roberts, M.D., F.R.S., and the late Mr. F Baden Benger F.I.C., F.C.S. in 1880, since when it has been the premier dietetic preparation of its kind in the British Empire.

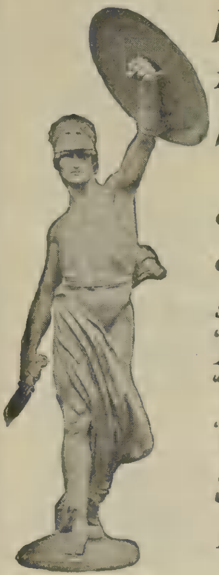
Notes on Liquid Paraffin.



THE MEDICAL MAN requires accuracy and precision in all matters of prescribing. The British Pharmacopoeia (1914) says that LIQUID PARAFFIN must have a specific gravity 0·860 to 0·890. Does this specification lead to the patient receiving an oil, or oils, of definite physical properties or known therapeutic values?

In THE LANCET (Nov. 1915) Professor R.A. Bolam of Newcastle-on-Tyne, England, quoted three cases of white oils all having this same specific gravity: 0·884 at 60°Fahr.

"A" had a viscosity or "body" of 12 times water.
"B" a viscosity of 17·2 times water.
"C" a viscosity of 2·7 times water.

So PARAFFINUM LIQ: of "884" specific gravity might mean your patient received an extremely viscous oil (17·2) or the right oil (12) or one so thin that with an ordinary dose, anal leakage would be inevitable.

This is not accurate standardization and such specifications lead to confusion.

(To be Continued)

Our Perfectly Refined pure Russian Liquid Paraffin *Russolax*

IS RELIABLE, RECOGNISED UNIFORM & STANDARDIZED.

DETOXICATED VACCINES

(Prepared by GENATOSAN LTD.)

IMPORTANT NOTICE.

IT is most essential, to ensure successful treatment, to employ a vaccine which is *actually detoxicated.* All Vaccines sent out by us have been detoxicated personally by the discoverer of the process.

A goodly number of the leading Venereal Experts in London, Edinburgh, Brussels, &c., are using our Detoxicated Gonococcal Vaccine, and one of them, writing in the *Practitioner,* Jan., 1920, claims that it is "the best obtainable," and marks an "extremely important advance in vaccine therapy."

Since the discovery of the detoxication of the gonococcus, the process has been applied with equal success to most of the other pathogenic organisms.

Detoxicated Vaccines (Polyvalent) are now prepared by us for:—

I. Influenza and Pneumonia.

II. Common Colds and Catarrhs—*e.g.*, Coryza and Bronchitis, &c.

III. Gonococcus Infections—(A) Pure Gonococcal Vaccine for Acute Gonorrhœa, Gonorrhœal Rheumatism, and Epididymitis. (B) Gonococcus + Secondary Organisms, for Gleet, Prostatitis, and other Chronic Gonorrhœal Infections.

IV. STAPHYLOCOCCUS INFECTIONS *e.g.*, Acne, Furunculosis, Boils, Abscesses, Osteo-Myelitis, &c.

DETOXICATED VACCINES—*(continued)*

V. STREPTOCOCCUS INFECTIONS
Abscesses, Septicæmia, Puerperal Fever, Erysipelas, Rheumatism, and Arthritic Affections, Pyorrhœa and Tonsillitis, &c.

VI. BACILLUS COLI INFECTION
e.g., Cystitis, Pyelitis and Bacilluria, Colitis, &c.

VII. TUBERCULOSIS — Limited quantities of Detoxicated Tubercle Bacillus are now available.

VIII. Cerebro-Spinal Meningitis.

These Vaccines can be given with safety not only for Prophylactic, but also for Curative Purposes. Their non-toxicity renders them *specially suitable* for administration during the course of an *acute infection.*

CURE TESTS FOR GONORRHŒA.

PROVOCATIVE VACCINE & ANTIGEN.

We are now able to supply a special form of Non-toxic Gonococcal Vaccine, which is not only of therapeutic value, but which also acts as a powerful provocative test for cure.

In addition we supply a superior form of Gonococcal Antigen for use in the Complement Fixation Test.

Particulars may be obtained on Application to

GENATOSAN LIMITED

(British Purchasers of The Sanatogen Company),

The 'Allenburys' Milk Food No. 2 -	3·06	1·0	0·81

"It is a fatal error to expect the milk of a foreign species to be immediately adapted to and utilized by the human infant; the differences between that of the woman and that of a lower animal would indicate, even when given to the newly born with normal functions, that we must wait until the delicate digestive and assimilative organs can make use of the material designed for a more vigorous animal."

—*Dr. Henry L. Coit at the English Speaking Conference on Infant Mortality.*

It follows that until such time as the digestion is developed the best food is that which approximates most closely in its composition to the maternal milk.

TRADE MARK A.D. 1715

BACTERIAL VACCINES

prepared in the Department for Therapeutic Inoculation, St. Mary's Hospital, London, W.—Director: Sir A. E. Wright, C.B., M.D., F.R.S., etc.

The undermentioned Vaccines are supplied in bulbs containing 1 c.c., and in rubber-capped bottles containing 25 c.c. The dilutions marked with an asterisk are also supplied in rubber-capped bottles containing 10 c.c.

ACNE BACILLUS VACCINE.
In dilutions containing 10 or 20* million acne bacilli *per c.c.*

MIXED ACNE VACCINE, 'A.'*
1000 million Staphylococcus albus and 10 million acne bacilli *per c.c.*

MIXED ACNE VACCINE, 'B.'*
500 million S. albus and 20 million acne bacilli *per c.c.*

ACTINOMYCOSIS VACCINE.
Each c.c. contains 25 million mycelial fragments.

ANTI - CATARRH VACCINE (Prophylactic).*
Each c.c. contains: 100 million B. pneumoniæ (Friedländer), 50 million Pneumococcus, 500 million Staphylococcus, 100 million M. catarrhalis, 50 million B. septus (diphtheroid), 300 million B. influenzæ, and 12 million Streptococcus. Also see "Anti-Influenza Vaccine" and "Mixed Vaccine for Colds."

ANTI-CHOLERA VACCINE (Prophylactic)†
In dilutions containing 1000 or 2000 million V. choleræ *per c.c.*

ANTI - INFLUENZA VACCINE, MIXED (St. Mary's Hospital Formula).
Each c.c. contains: 500 million B. influenzæ, 1000 million Pneumococcus (mixed types), and 100 million Streptococcus. Also see "Anti-Catarrh Vaccine" and "Influenza Bacillus Vaccine."

ANTI - INFLUENZA VACCINE (Army Formula).
Each c.c. contains: 60 million B. influenzæ, 200 million Pneumococcus, and 80 million Streptococcus.

ANTI - INFLUENZA VACCINE (Wynn's Formula).
Each c.c. contains: 100 million B. influenzæ, 100 million Pneumococcus, and 100 million Streptococcus.

ANTI-MENINGOCOCCUS VACCINE (Prophylactic).
Each c.c. contains: 1000 million D. intracellularis meningitidis.

ANTISEPSIS VACCINE.
Each c.c. contains: 1000 million Staphylococcus, 35 million Streptococcus fæcalis, and 15 million S. pyogenes.

ANTI-TYPHOID VACCINE (Prophylactic).
In dilutions containing 1000 or 2000 million B. typhosus *per c.c.* Also see "Typhoid Vaccine."

ANTI-TYPHOID-PARATYPHOID VACCINE (T.A.B.).†
Each "first dose" contains 500 million B. typhosus, 250 million B. paratyphosus A, and 250 million B. paratyphosus B, *in 1 c.c.*; each "second dose" contains double these numbers *in 1 c.c.**

ANTI-TYPHOID-PARATYPHOID-CHOLERA VACCINE.†
Each "first dose" contains 500 million B. typhosus, 250 million B. paratyphosus A, 250 million B. paratyphosus B, and 1000 million V. choleræ *in 1 c.c.*; each "second dose" contains double these numbers *in 1 c.c.*

BORDET BACILLUS VACCINE.
In dilutions containing 250 or 2000 million Bordet's bacilli *per c.c.* Also see "Whooping Cough Vaccine."

GONOCOCCUS VACCINE.
In dilutions containing 5, 20, 50* or 200 million Gonococci *per c.c.*

INFLUENZA BACILLUS VACCINE.
In dilutions containing 100, 500 or 1000* million B. influenzæ *per c.c.* Also see "Anti-Influenza Vaccine."

MICROCOCCUS MELITENSIS VACCINE.
Each c.c. contains 100 million cocci.

MIXED VACCINE FOR COLDS.*
Each c.c. contains: 30 million M. catarrhalis, 30 million Pneumococcus, 300 million B. influenzæ, 300 million Staphylococcus, 50 million B. septus (diphtheroid), 12 million Streptococcus, 50 million B. pneumoniæ (Friedländer). Also see "Anti-Catarrh Vaccine."

MIXED VACCINE FOR COLIFORM INFECTIONS.
Each c.c. contains 100 million B. coli communis, 100 million B. coli communior, 40 million B. lactis aerogenes, and 20 million B. acidi lactici.

PARODONTAL STREPTOCOCCUS VACCINE *
Each c.c. contains 30 million Streptococci.

PNEUMOCOCCUS VACCINE.
In dilutions containing 20, 50* or 200 million Pneumococci *per c.c.*

STAPHYLOCOCCUS VACCINE.
In dilutions containing 100, 500, or 1000* million Staphylococci *per c.c.* Also see "Antisepsis Vaccine."

STREPTOCOCCUS VACCINE.
In dilutions containing 5, 20* or 100 million Streptococci *per c.c.* Also see "Antisepsis Vaccine."

TUBERCLE VACCINE (Tuberculin: Bacillary Emulsion).§
In dilutions containing 1/100,000; 1/40,000; 1/25,000; 1/20,000; 1/5,000; 1/2,000; 1/1,000; 1/500; 1/200; or 1/100 mgm. of powdered tubercle culture *per c.c.*

TYPHOID VACCINE (For Treatment).
Each c.c. contains 100 million B. typhosus. Also see "Anti-typhoid Vaccine."

WHOOPING COUGH VACCINE.
Each c.c. contains 250 million Bordet's bacilli and 10 million Pneumococci. Also see "Bordet Bacillus Vaccine."

* * *

"POLLACCINE" (Pollen Vaccine).
In dilutions containing 5, 20, 100 or 500* units of pollen toxin *per c.c.* Applicable for prophylaxis or treatment of hay fever, the dose to be regulated according to individual susceptibility by means of the HAY FEVER REACTION OUTFIT by which, also, it may be determined whether suspicious symptoms are those of true hay fever or not.

---

† The 1 c.c. bulbs of this vaccine are supplied in sets of two doses as required for one individual, and only the stronger of the dilutions is supplied in bottles.

§ The 1 c.c. bulbs of Tubercle Vaccine are supplied in sets of three bulbs of any one dilution.

* This vaccine is also supplied in bottles of 10 c.c.

A Pamphlet on "Vaccine Therapy" will be forwarded on request.

Sole Agents for the sale of the above-mentioned Vaccines:

PARKE, DAVIS & Co., 50-54, BEAK ST., REGENT STREET, LONDON, W. 1.

Telegraphic and Cable Address: "CASCARA, LONDON." Telephone: REGENT 3260 (6 lines).

CARNRICK'S

"LIQUID PEPTONOIDS"

(Prepared by predigestion from Beef, Wheat, and Milk.

PROPERTIES.

"**Liquid Peptonoids**" combines the properties of a gentle stimulant with those of a powerful nutrient, in the form of a delicately flavoured cordial.

It is **Aseptic** and highly dialysable, the nutrient bases being in a condition for immediate absorption into the blood without any effort on the part of the patient. It is well tolerated by the stomach and sustains life when all other means have signally failed.

Its complete diffusibility renders it a perfect nutrient for colonic alimentation, and, when properly administered, it is capable of supporting life alone in this manner for considerable periods.

INDICATIONS.

In Crises and exhausted conditions as a dialysed nutrient, when it is absolutely essential for the preservation of life to get nutriment into the blood quickly, without undergoing digestion.

In all cases of gastro-intestinal disease, like Gastric Ulcer, Typhoid Fever, Colitis, etc., where it is desired to leave little or no accumulating residue in the stomach.

In Marasmus and other wasting diseases

In the vomiting of Pregnancy.

As a Tonic Peptogenic Food during convalescence after severe illness.

In Pneumonia.

As a Colonic Nutrient, either alone or in conjunction with other foods, or with saline in surgical cases.

"DRY PEPTONOIDS" SOLUBLE (Carnrick & Co.)

BEEF, WHEAT, and MILK PRE-DIGESTED by ENZYMES.

ALMOST ENTIRELY SOLUBLE, EVEN IN COLD WATER.

Contains :—Mineral matter, 8·2 per cent. ; proteins, 38·80 per cent. ; carbohydrates, 48·00 per cent.——"The preparation is one of distinct merit, and should serve as a rapid nutrient, especially in cases of digestion enfeebled by illness."—*The Lancet.*

"DRY PEPTONOIDS" SOLUBLE is indicated as a nutritive reinforcement in Convalescence and all conditions of Enfeebled Digestion.

CARNRICK & CO., Limited, 183, Acton Vale, London, W. 3,

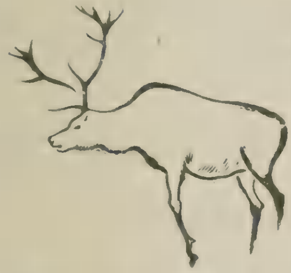
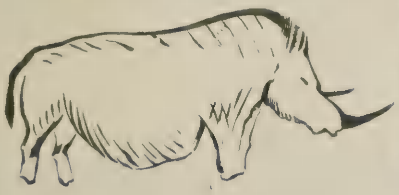
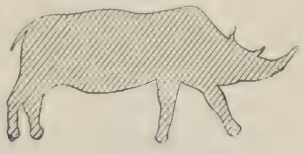


FIGURES EXEMPLIFYING A LATER STAGE IN THE HISTORY OF AURIGNACIAN PAINTING.—Following the artists who painted only the outlines of their pictures came pioneers who attempted some degree of modelling in colour. Two examples of their handiwork are here reproduced; the outlines, strokes and shading indicate the coloured portions—red in both cases. The rhinoceros is from a cavern in Dordogne, the stag from the walls of a Spanish cave. Both are remarkably lifelike, despite the fact that the artist has not yet learned to represent more than three legs, and that the antlers of the stag are depicted in full, whereas the animal itself is drawn in profile.

The Bushmen of to-day show a remarkable cultural likeness to the Aurignacians and are often referred to as their present-day representatives. They live in caves, on the walls of which they paint pictures in much the same fashion as did the Aurignacians.



For purposes of ethnographic comparison, a Bushman cave-painting, in red, of a rhinoceros, is here introduced. While certain of their animals are drawn with great skill, the Bushman paintings are—in general—far from equalling in perfection those of the Palaeolithic artists of the best period.



CULTURE PHASE: PALAEOLITHIC
(Aurignacian division)

COPYRIGHT

HORMOTONE

IN GYNECOLOGY.

Owing to the reciprocal relationship that exists between the glands of internal secretion, a functional disorder of them is, in its last analysis, always a pluriglandular disturbance—never a monoglandular malady. As Blair Bell puts it: "A woman is what she is on account of the sum total of her internal secretions."

HORMOTONE **is a pluriglandular preparation of proven** value in

MENSTRUAL & MENOPAUSAL DISORDERS

The following Reports from Physicians are of interest:

"I used Hormotone with satisfactory results in a case of amenorrhea. The nervous symptoms, which were alarming, were promptly corrected and the menstrual flow restored."

"I have used Hormotone in the case of a young lady suffering from dysmenorrhea, fainting and prostration at period, which was the cause of her losing her position as stenographer. After being on Hormotone for five months she is entirely free from pain and there is a notable gain in her general condition of nutrition."

"I have noted exceptionally good results with Hormotone in that type of neurasthenia associated with the menopause."

In Menopausal Conditions associated with Hypertension, use

HORMOTONE WITHOUT POST-PITUITARY.

Dose of either preparation: One or two tablets three times daily before meals.

NEW YORK, U.S.A. **Hornsey, LONDON, N.8.**

Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum,** in the **Wasting** and **Febrile Diseases** of **Children,** and in the treatment of **Weak Babies,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospitals for Children.

Diseases of Children.

Thos. N. Vincent, M. D., *Visiting Physician St. Ann's Infant Asylum, Washington, D. C.:* "I have used Valentine's Meat-Juice in St. Ann's Infant Asylum, in the treatment of cases of Diarrhoea, incident to Teething in infants of delicate constitutions, and find it in every way satisfactory. It is easily assimilated, attended with no untoward symptoms and agrees in cases where other foods fail and when milk, prepared in any way used at present, also failed. I can testify also to its usefulness as a nutrient in Scarlet Fever and Measles."

W. B. Scranton, M. D., *Medical Superintendent Korean Mission Methodist Episcopal Church, Seoul, Korea:* "A most excellent use I frequently put Valentine's Meat-Juice to is tiding Babies through Cholera Morbus and the Wasting diseases incident to Summer and Inanition. It acts at once, and many a crisis has been passed safely by my patients through the agency of Valentine's Meat-Juice. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhœa known as Sprue, where it tides the patients over until they can get to a better climate, and the change of climate rectifies the rest."

Dr. Raphael Raimondi, *Consulting Physician to the Montmartre Nurseries, Paris, France:* "I use Valentine's Meat-Juice with Nurslings eighteen months to two years old. These very weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty gramms of boiled water twice a day, and to be continued for a month."

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

For Sale by European and American Chemists and Druggists

BOOTS PURE DRUG COMPANY LIMITED,

MANUFACTURING CHEMISTS AND
MAKERS OF FINE CHEMICALS. **NOTTINGHAM.**

SIR JESSE BOOT, Managing Director.

Vitamogen
VITAMINES
Regd.

VITAMOGEN represents a highly Concentrated Food, and contains Free Vitamines in a natural and unchanged condition.

VITAMOGEN has been found invaluable in Cases of Depression following INFLUENZA.

VITAMINES.

"The **Vitamines** are bodies which, until recently, have been little known and less understood. Even now our appreciation of their behaviour under certain circumstances in the impure state is far in excess of our knowledge of their true character and actual essential composition.

Physically, chemically, and structurally they are delicate substances, since heating above a relatively low temperature irretrievably destroys their activity (sterilising).

Deficiency diseases caused by the absence of **Vitamines** yield rapidly to a course of **Vitamine**-rich diet. Such a diet will not only prevent the occurrence of **Rickets** and Scurvy—and, to go further, Beri-Beri and Pellagra—but is the best, in fact the only, treatment to arrest the progress and cure these conditions, except in so far as any definite anatomical deformities of the bony parts have taken place. These are, of course, only amenable to orthopædic and surgical treatment. It is therefore essential to prevent the occurrence of any crippling malformations by promptly assuring a **Vitamine**-rich pabulum for the organism.

When we try to define the exact composition of **Vitamines** we are unable to do so at our present state of knowledge. We can extract the active principle from certain foods naturally rich in **Vitamines,** but so elusive are the essential **Vitamine** principles that they have not yet been isolated. An extract of this sort, presenting all the active and valuable properties of the **Vitamine** principles in a condensed form, is **VITAMOGEN**.

By its addition, any food that is palatable and assimilable can be made nutritious and powerfully reparative to tissue waste. The **Vitamines** presumably act, in part at any rate, by hormonically activating the internal secretions of the essential auxiliary digestive organs."

Vitamogen is useful in any form of **Nervous Disease — Neurasthenia — Shell Shock — Hysteria—Anæmia—Nervous Dyspepsia**—and all **Wasting Diseases—INFLUENZA**—and for its great Tonic-effect in **convalescence after severe illness**, owing to its properties of aiding the body to form fresh tissues to replace those which have been wasted, **Sleeplessness —Malnutrition** and the **effects of overwork** and **Nervous break-down.** It is indicated where a **Tendency to Rickets** or **Dental Caries** is manifested.

__Vitamogen__ is packed in two sizes—__2/9__ and __5/9__, or in bulk for Hospitals. Literature on the __Vitamines__ will be sent upon application to VITAMOGEN, Ltd., 24/26, Holborn, London, E.C. 1.

THE LANCET ANALYSIS.

Moisture, 7·00; mineral matter, 7·50 (equal to 2·50 phosphoric acid); protein, 24·96 per cent.; sugar, 20·83; starch, 26·25; fat, 1·61; cellulose or fibre, 11·95. The preparation is largely soluble in cold water, the total soluble matters amounting to 62·80 per cent. VITAMOGEN also contains, as will be seen from the analysis, a rich proportion of phosphoric acid.

CHELTINE DIABETIC FOODS

THE CHELTINE FOODS CO., CHELTENHAM, beg to state that, in order to keep faith with the medical profession, their Foods for ordinary chronic Diabetic cases are not sold as entirely starchless; though the starch is transformed, by a very special and original process of manufacture, into a more easily assimilable carbohydrate **which nourishes the patient without aggravating the manifestations of the disease.** The patient for whom any Cheltine Diabetic Foods are prescribed does not, therefore, suffer from the small quantity of specifically treated starch they contain, but benefits materially because Cheltine Flour, Food, Rusks, Biscuits, &c., present more nourishing value than otherwise would be the case, besides being so very palatable and appetising. The actual results obtained from these Cheltine Diabetic Foods for Diabetics leave no room for doubt that in the majority of cases they are a general ameliorative when taken under the direction and control of the patient's medical adviser, who realises that every case of diabetes must be treated on its merits. Present-day practice in this direction is gradually eliminating old-time theory.

For extreme or acute cases, mostly in young persons, many of our medical friends have for years asked us also to manufacture a **"Starchless"** Flour and Foods. Our great aim has been to do this—provided we could produce such Foods sufficiently nutritious. At last, after years of research, we have been able to accomplish this desirable feature. And for severe cases where Medical Practitioners insist upon what is as nearly as possible a "Starchless" regimen, we therefore now offer our Cheltine Diabetic Strict-Diet Flour and Foods.

Members of the Profession may obtain Free Samples and all information by writing

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps, the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ CO. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water

MEDICAL OPINIONS.

"I have tried your Mist. Damianæ Co. considerably in the dyspepsia of commencing phthisis, and can very strongly recommend its use in those cases. It soothes the stomach wonderfully, and enables the patient to take more food whilst acting as a powerful stimulant in relieving exhaustion."—Yours faithfully, W. H. B——, B.A. (Cantab.), M.R.C.S., L.S.A.

THE MEDICAL ANNUAL.—"Damianæ is not used so frequently in this country as in America, where its value as a tonic for Neurasthenia is well known. Messrs. HEWLETT & SON put up a very excellent preparation of this drug, combined with Nux Vomica and simple aromatics and bitters, which is valuable for dispensing, and yields very satisfactory results in treatment."—1898.

Dr. M——, R.N., writes:— "Farnham (Hants.), Sept. 1903.
"I have frequently prescribed your Mist. Damianæ Co. and proved it efficient in treating Neurasthenia."

Packed in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

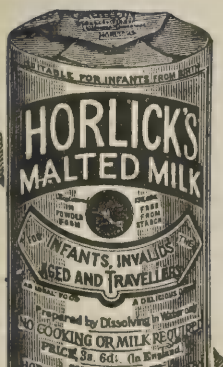
Price in England, 12/[illegible] per lb.

Introduced and Prepared only by—

C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte St., LONDON, E.C.

HORLICK'S MALTED MILK

THE IDEAL FOOD FOR INVALIDS AND CONVALESCENTS



SUITABLE FOR INFANTS FROM BIRTH
HORLICK'S
MALTED MILK
FOR INFANTS, INVALIDS, AGED AND TRAVELLERS

A MOTHER WHO KNOWS

"BABY has thriven exceedingly well," writes an Enfield mother about her little boy, 9 months old: "I have never had one day's trouble with him since putting him on Nestlé's Milk. I fed him myself for the first two months, but he did not seem to get on well at all, so I decided to put him on Nestlé's Milk and am ever thankful. Baby's health is excellent. He is a big and bonny boy, very strong for his age, very good all night, and very contented."

Why did this mother put her baby on Nestlé's Milk?

Here is the answer in her own words:—

"I have four children, three of which have been reared entirely on Nestlé's Milk, and have found it at all times splendid. My oldest boy did not have Nestlé's Milk, but I tried five or six other baby foods, and shall never forget the dreadful time I had with him."

NESTLE'S MILK MEANS HEALTH FOR BABY AND HAPPINESS FOR MOTHER.

KEROL

KEROL combines all the properties which go to the making of an ideal preparation.

It has been shown to be practically non-toxic, non-irritant and non-corrosive—a combination of properties which make it the one preparation which can be used with perfect confidence wherever the use of either a disinfectant or antiseptic is indicated. It is of high and definite germicidal value and is perfectly homogeneous

KEROL is highly recommended by Bacteriologists and by prominent members of the Medical Profession.

KEROL CAPSULES

INTESTINAL. *These are of great value where intestinal antisepsis is indicated. In a comparatively short space of time the coli content of the intestine is reduced by over 99 per cent. They are non-irritant and perfectly safe*

STOMACHIC. *For use in cases of stomach fermentation and other gastric troubles, and are of great value in reducing the number of malign organisms prior to administration of treatment with lactic ferments, i.e., sour milk, etc.*

Samples and literature sent free to any Medical Practitioner

QUIBELL BROS. LTD

NEWARK

Point 3.

Kerocain does not Irritate the Tissues.

INVESTIGATORS unanimously agree that Novocain (with which Kerocain is chemically, physiologically and therapeutically identical) is excelled by no other local anaesthetic in the important respect of freedom from tissue-irritation. Kerocain in fact does not irrirate the tissues at all.

Varying degrees of tissue-irritation are, on the other hand, disclosed in the published records of most other local anaesthetic agents. Prof. Braun, for instance, goes so far as to state in his text-book that "On account of this important requirement many of the newer anaesthetics have failed in their purpose."

Freedom from tissue-irritation is one, but by no means the only, ground for Kerocain's claim to be considered the local anaesthetic of choice. Other distinguishing features of Kerocain as a local anaesthetic are its negligible toxicity, its rapid penetration, easy sterilisibility, compatibility with Adrenalin, and freedom from the risks of habit-creation. This anaesthetic is the only substitute for Cocaine which was considered by the recent Commission on Cocaine.

A free copy of our illustrated booklet on "The Theory and Practice of Local Anaesthesia and Anoci-association" will be sent to any Surgeon on request.

AËRATED LIME-WATER

An efficacious Remedy for Nausea and Sickness. Mixed with milk, forms a valuable Beverage for Ladies nursing or Delicate Children.

Prepared & Sold in Syphons & Botts by R. HOGG & SON, 1, Southwick-st. W

GRADE A MILK

THE FOOD CONTROLLER, in conjunction with the Ministry of Health and the Scottish Board of Health, will issue licences, becoming operative on March 15th, permitting the use of the designations "Grade A (Certified)" and "Grade A" in connection with the sale of milk. (Existing licences in regard to Grade A and Grade B will lapse on March 15th.)

Grade A (Certified) Milk must be bottled on the farm where it is produced, and must not contain at any time before reaching the consumer more than 30,000 bacteria per cubic centimetre or bacillus coli in one tenth cubic centimetre.

Grade A Milk must be delivered by dealers in the vessels in which they receive it or in bottles filled on the dealers' premises.

Both Grade A (Certified) and Grade A Milk must be produced by herds that contain no animal that reacts to the tuberculin test, on farms that obtain for Dairy equipment and methods not less than 300 out of a possible maximum of 500 marks on the Government Inspection Report Card.

Further information can be obtained by application to the SECRETARY,

Experimental Physiology—May L. Walker, M.A., B.Sc., M.B.
Physiology of the Nervous System—A. Ninian Bruce, M.D., D.Sc.
Experimental Pharmacology—W. C. Sillar, M.D., B.Sc.
Pathology, Practical—D. Murray Lyon, M.B.
Physics—G. A. Carse, M.A., D.Sc.
Diseases of the Larynx, Ear, and Nose—A. Logan Turner, M.D., J. Malcolm Farquharson, M.B.
Tropical Diseases—D G. Marshall (Lt.-Col., I.M.S.).
Medical Entomology and Protozoology—J. H. Ashworth, D.Sc., F.R.S.
Tropical Hygiene—J. B. Young, M.B., D.Sc. (conjointly with Professor).
Diseases of the Skin—Norman Walker, M.D., Frederick Gardiner, M D.
Clinical Instruction in Infectious Fevers—Alexander James, M.D., Claude B. Ker, M.D.
History of Medicine—J. D. Comrie, M.A., B.Sc., M.D.
Neurology—Edwin Bramwell, M.D.
Physical Methods in the Treatment of Disease—Harry Rainy, M.A., M.D.
Surgical Pathology—J. M. Graham, M.B., Ch.M.
Practical Anæsthetics—J. Stuart Ross, M.B., Ch.B., *Demonstrator.*

Practical Instruction is afforded, under the superintendence of the Professors, in Laboratories, with the necessary appliances, and in Tutorial and Practical Classes connected with the above Chairs, and opportunities are afforded to Students and Graduates to extend their practical knowledge and engage in original research.

Opportunities for Hospital Practice are afforded at the Royal Infirmary, the Hospital for Sick Children, Maternity Hospital, the City Fever Hospital, and the Asylum for the Insane. Upwards of 2160 beds are available for the Clinical Instruction of Students of the University.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh, viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); and Diplomas in Special Branches of Medical and Surgical Practice may also be conferred on Graduates in Medicine and Surgery of the University, and to approved registered practitioners.

The minimum Class Fees for M.B. and Ch.B., including Hospital Fee (£12), amount to about £150, and the Matriculation and Examination Fees to £28 7s. An additional Fee of £15 15s. is payable by those who proceed to M.D., and £15 15s. by those who proceed to Ch.M.

The annual value of the Bursaries, Prizes, Scholarships, and Fellowships in the Faculty of Medicine amounts to about £3600, and that of the other Bursaries, &c., tenable by Students of Medicine, amounts to about £1820.

Instruction is also given in Public Health, and the Degrees of B.Sc. and D.Sc. in Public Health and a Diploma in Public Health are conferred by the University.

A Syllabus and further information as to Matriculation, the Curricula of Study for Degrees, &c., may be obtained from the Dean of the Faculty of Medicine; and for Degrees in the Faculties of Arts, Science, Divinity, Law, and Music, from the Deans of these Faculties, or from the Clerk of Senatus; and full details are given in the University Calendar, published by James Thin, 55, South Bridge, Edinburgh. Price by post, 5s. 6d.

By Authority of the Senatus.

FOR LONDON UNIVERSITY

MATRICULATION

OPEN TO ALL

The Hall-Mark of a Sound Education.
The Key to all the learned Professions.

Matriculation exempts candidates from the Preliminary Examination in Medicine and for entrance to nearly all the Professions.

OTHER ADVANTAGES OF MATRICULATION

London Matriculation is open to persons of both sexes above the age of 16, without conditions of residence or method of preparation.

Every Candidate for a Degree at London University (except Graduates and holders of specified certificates) must pass matriculation.

London Matriculation is generally recognised as being the most valuable Examination in the world.

16th March, 1920. A. ERNEST WILKES, Secretary.

St. Thomas's Hospital.—Applications are invited for following appointments in the Venereal Department :—

Two SENIOR ASSISTANT MEDICAL OFFICERS at £600 per annum.

Two JUNIOR ASSISTANT MEDICAL OFFICERS at £350 per annum.

One BACTERIOLOGIST at £600 per annum.

All appointments are for twelve months and renewable annually.

The Department will be open from 8 A.M. to 10 P.M. daily (Sundays excepted), and two Assistant Medical Officers will be on duty at one time.

Candidates for posts [illegible] Assistant Medical Officers should stat whether, in the event of their not being appointed to one of the Senior posts, they are willing to serve in one of the Junior.

Applications, stating age, qualifications, and experience, with copies of three testimonials, to arrive not later than Monday, March 29th, should be addressed to the Secretary, St. Thomas's Hospital, Albert Embankment, S.E. 1.

Metropolitan Borough of Greenwich. Appointment of ASSISTANT MEDICAL OFFICER OF HEALTH and MEDICAL OFFICER FOR TUBERCULOSIS DISPENSARY.—The Council of the above Borough will, at its meeting to be held on the 28th April, 1920, or at [illegible] adjournment thereof, proceed to the appointment of [illegible] Assistant Medical Officer of Health and Medical Officer to take charge of the Tuberculosis Dispensary, and applications are invited for the appointment.

Candidates must be registered Medical Practitioners, have held [illegible] house appointment for at least six months in [illegible] general hospital, have special practical experience in modern forms of treatment of Tuberculosis, in [illegible] sanatorium or otherwise, and must have had practical experience in bacteriological laboratory work. Candidates must have [illegible] Diploma in Public Health.

The person appointed will have charge of the Tuberculosis Dispensary under the administrative direction and control of the Medical Officer of Health, shall be personally responsible for the diagnosis and treatment of all patients at the Dispensary, shall carry out the duties of Tuberculosis Officer, and shall visit for the purpose of keeping observations on his own patients, but not generally for domiciliary treatment. He shall be available for consultation with general practitioners, and [illegible] and when provided shall act as Medical Officer to the Home of Rest and Tuberculosis Working Centre.

He shall perform such duties [illegible] may be considered necessary by the Medical Officer of Health.

The commencing salary will be at the rate of £700 per annum, rising by £50 per annum to [illegible] maximum salary of £900, to include all present and future bonuses.

The successful candidate will be required to devote the whole of his time to the service of the Council, shall not engage in private practice, and shall reside within the Borough.

The appointment will be terminable by three months' notice on either side, and the person appointed shall not on retirement claim or be entitled to any superannuation.

Applications must be made on forms to be obtained from the undersigned, stating age, qualifications, and experience, accompanied by not more than three recent testimonials, and must be sealed up and endorsed outside "Medical Officer," and must reach me not later than 10 a.m. on Friday, 9th April, 1920.

Canvassing members of the Council, either directly or indirectly, will be [illegible] disqualification, but there would be no objection to [illegible] candidate, if he so desires, sending copies of his application and testimonials, which may be addressed to the Town Clerk.

FREDERICK J. SIMPSON, Deputy Town Clerk.

Burton-on-Trent Infirmary.—House SURGEON.—The Committee require the services of a duly qualified Resident House Surgeon. Salary £200 per annum, plus honorarium, with comfortable rooms and board. Duties to commence immediately. Applications, stating age and experience, and accompanied by copies of testimonials, to be sent to the undersigned not later than April 1st, 1920.

The Infirmary, Burton-on-Trent. JOHN WOOD, Hon Sec.

House Surgeon wanted at the Hos-PITAL, Tiverton, Devon. Salary £100 per annum, with rooms, board, and laundry. Leisure for reading. Apply to the Hon. Sec.

Wolverhampton and Staffordshire GENERAL HOSPITAL.—A HOUSE SURGEON wanted for April 7th. The Hospital contains 210 beds, including the usual special departments, and is recognised by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice. Candidates must be registered under the Medical Acts.

The appointment is for six months, with a salary at the rate of £200 per annum; board, furnished rooms, and laundry provided.

Application, with copies of testimonials, to the undersigned.

W. H. HARPER, House Governor and Secretary.
Wolverhampton, 23rd March, 1920.

Gravesend Hospital. — House SURGEON.—Applications are invited from fully qualified Men for the above post.

The Hospital contains 72 beds and cots, and has an Out-patient and Casualty Department.

Owing to the unique situation of the Hospital, at the entrance to the Port of London, many accidents and interesting cases are treated, and the post affords an excellent opportunity for Surgical experience.

Salary £200 per annum, with board, residence, and laundry, will be paid to the successful applicant.

Applications, with copies of three recent testimonials, should be sent to the undersigned immediately.

March 23rd, 1920. C. E. CHAPMAN, Secretary.

Salford Royal Hospital (272 beds).— Applications are invited for the following vacancies, which will occur in the Resident Medical Staff (Male) on the 31st March next:—

RESIDENT SURGICAL OFFICER. Salary at the rate of £250 per annum.

HOUSE SURGEON. Salary at the rate of £150 per annum.

The appointments are for a period of six months, with board and residence.

Candidates must be registered under the Medical Act.

Applications, stating age and qualifications, together with copies of testimonials and certificate of registration, to be addressed to the undersigned without delay. By order of the Board.

GEORGE RUDDLE,
March 22nd, 1920. General Superintendent and Secretary.

Gloucestershire Royal Infirmary and EYE INSTITUTION.—Applications are invited for the posts of HOUSE PHYSICIAN and ASSISTANT HOUSE SURGEON (Males). The appointments are for six months, which may be extended for similar periods by re-election from time to time.

Salaries at the rate of £175 and £150 per annum respectively, with board, residence, and laundry.

Candidates should send in their applications, stating age, and accompanied by not less than three testimonials of recent date, to the Secretary.

These posts are open to Senior Students who are about to become qualified.

The elected candidates will be required to enter upon their duties at once.

Gloucester, March 23rd, 1920. G. HURFORD, Secretary.

Monmouthshire County Council.— LADY ASSISTANT MEDICAL OFFICER.—The Council invite applications from Female registered Medical Practitioners for the appointment of Assistant Medical Officer for duties mainly in connexion with the Council's scheme of Maternity and Infant Welfare.

Salary £500 per annum, rising by annual increments of £25 to £700, with necessary travelling and out-of-pocket expenses.

The successful candidate will be required to act under the immediate direction and supervision of the County Medical Officer, to devote her whole time to the service of the Council, and to reside within such place as the Council may determine.

A schedule of the duties to be performed, together with conditions of appointment and a form of application, can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by the 7th April, 1920. D. ROCYN JONES, County Medical Officer.

County Hall, Newport, Mon., 22nd March, 1920.

Surrey County Council.—Appointment of ASSISTANT MEDICAL OFFICER OF HEALTH.—The Surrey County Council invite applications for the appointment of an Assistant Medical Officer of Health at a salary, based on existing economic conditions, of £600 per annum, with reasonable travelling expenses.

Candidates must be registered Medical Practitioners, not over forty years of age, with Public Health qualifications. Preference will be given to those who have had practical experience of the work of a Medical Officer of Health.

The officer appointed will be required to assist generally in the work of a Public Health Department under the supervision and control of the County Medical Officer of Health, and to devote his whole time to his official duties.

The appointment will be held during the pleasure of the Council, be subject to a quarter's notice by the person appointed, and will not carry with it any right to a superannuation allowance.

Applications, stating age, qualifications, and previous experience, together with copies of not more than three recent testimonials, and endorsed "Assistant Medical Officer," must be received by the undersigned not later than 6th April, 1920. Selected candidates will be interviewed on 20th April, 1920. Canvassing is prohibited.

T. W. WEEDING, Clerk of the Council.
Dated this 17th day of March, 1920.

Birkenhead Borough Hospital.—Wanted, fully qualified SENIOR and JUNIOR HOUSE SURGEONS (Male). Salary £200 and £170, with board and lodging. Applications, with testimonials, to be sent in at once, Chairman of Weekly Board.

Norfolk and Norwich Hospital,

NORWICH.

CASUALTY OFFICER (Male), in charge of fifty Surgical beds, required at the beginning of April.

Salary £200, with board, residence, and laundry.

Candidates, who must possess registered qualifications, should forward applications, stating age, nationality, &c., together with copies of testimonials, as soon as possible, to the undersigned.

12th March, 1920. FRANK INCH, Secretary.

Stockport Infirmary.—Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER. The gentleman appointed must be duly qualified in Medicine and Surgery, and registered under the Medical Acts. Salary £200 per annum, with board and apartments.

Applications, stating age, qualifications, and experience, with copies of testimonials, stating earliest day duties could be commenced, to be addressed to the undersigned.

EDWIN J. PEARCE, Secretary-Supt.

The Royal National Hospital for CONSUMPTION AND DISEASES OF THE CHEST, Ventnor, Isle of Wight.—A Male ASSISTANT RESIDENT MEDICAL OFFICER is required to take up duties at an early date. Salary £300 per annum, with board and lodging in the Hospital. Every candidate should be doubly qualified, registered, and unmarried, and should have knowledge of Bacteriological methods. Applications, stating age and qualifications (with one copy of three recent testimonials), may be sent at once to the Secretary, R.N.H.C., 18, Buckingham-street, Strand, London, W.C. 2.

Borough of Plymouth.—Assistant TUBERCULOSIS OFFICER.—Applications are invited for the appointment of whole-time Assistant Tuberculosis Officer, who will act primarily as Medical Officer in charge of the Udal Torre Sanatorium, Yelverton, and will be required to reside at Yelverton. Candidates must have had special experience in the Institutional treatment of Tuberculosis.

Salary £500 per annum.

Applications, stating age, qualifications, experience, &c., accompanied by copies of three recent testimonials, must reach me not later than the 12th April, 1920. O. HALL, Medical Officer of Health.

Town Hall, Stonehouse, Plymouth.

Manchester Hospital for Consumption and DISEASES of the THROAT and CHEST.—Wanted, a RESIDENT MEDICAL OFFICER for the In-patient Department, Bowdon, Cheshire. The duties include attendance on certain days at the Out-patient Department in Manchester and operations in the Throat Department of the Hospital. Candidates must be registered. Salary £350 per annum, with board, apartments, washing, and railway contract.

Applications, with copies of testimonials, to be sent in not later than April 9th to C. W. HUNT, Secretary.

Hardman-street, Deansgate, Manchester.

Ancoats Hospital, Manchester.

RESIDENT SURGICAL OFFICER (Male) required, to commence on or about April 15th next. Candidates must be duly qualified and registered. Salary £200 per annum.

For six months.

Applications, stating full particulars, to be forwarded to the undersigned, together with testimonials, by Monday, 5th April.

By order.

HEREERT J. DAFFORNE, Secretary.

Borough of Swindon.—Appointment of ASSISTANT MEDICAL OFFICER OF HEALTH.—The Corporation of Swindon invite applications from fully qualified Medical Practitioners (Male or Female) for the position of Assistant Medical Officer of Health, whose principal duties will be the Medical Inspection and Treatment of School Children and the work of Maternity and Child Welfare, at a commencing salary of £650 per annum, rising by annual increments of £50 to £750 per annum.

The person appointed will be required to devote the whole of his or her time to the duties of the office, and will not be allowed to engage in private practice, also to act under the superintendence of the Medical Officer of Health.

Candidates must have held a resident appointment at a recognised Eye Hospital for a period of not less than six months, and the person appointed should be an expert Refractionist, and able to undertake the work of a School Oculist.

Other conditions being equal, preference will be given to candidates possessing a Diploma in Public Health, and special experience in the X-Ray Treatment of Ringworm.

Excellent opportunities present themselves for gaining experience in the working of a modern Public Health Department, together with facilities for Pathological Research. The appointment will be terminable by three months' notice on either side.

Copies of definition of duties and forms of application may be obtained from the Medical Officer of Health, 61, Eastcott-hill, Swindon.

Applications, accompanied by copies of three recent testimonials, to reach the undersigned not later than Monday, the 12th April next, endorsed "Assistant Medical Officer of Health."

ROBT. HILTON, Town Clerk.

Town Hall, Swindon, 24th March, 1920.

Hereford County and City Mental HOSPITAL.—Wanted, a SECOND ASSISTANT MEDICAL OFFICER. Salary commencing £350 per annum, all found. Apply to Medical Superintendent.

Manchester Royal Eye Hospital.—JUNIOR HOUSE SURGEON required to enter duty April 15th. Salary £120, board and residence. Applications to be addressed to the Chairman of the Board of Management.

W. S. PROPHET, Secretary.

Royal Berks Hospital (220 beds).—Wanted, a HOUSE SURGEON, who must be fully qualified and registered. Salary £200 a year, with board, residence, and laundry. The appointment is for six months. Applications, with copies of recent testimonials, should be addressed to the undersigned.

27th March, 1920. HERMAN BURNEY, Secretary.

Glamorgan County Asylum, Bridgend.

JUNIOR ASSISTANT MEDICAL OFFICER required. Commencing salary (after deductions according to the Asylums Officers' Superannuation Act, 1909) £350, rising to £400 by annual increments of £25, with board, apartments, washing, and attendance.

Applications, stating qualifications, age, and nationality, with copies of recent testimonials, to be sent to the Medical Superintendent.

North Ormesby Hospital, Middlesbrough.—ASSISTANT HOUSE SURGEON required. Candidates must be duly qualified and registered. Salary at the rate of £175 per annum, with board, residence, and laundry.

Applications, stating age, together with copies of three testimonials, should be sent to the undersigned.

A. STANLEY BRUNT, Secretary-Superintendent.

General Hospital, Nottingham.—Wanted, CASUALTY HOUSE SURGEON. Appointment for six months. Salary at the rate of £150 a year, with board, residence, and laundry. Candidates are requested to send testimonials, with particulars as to age, qualifications, and experience, to the undersigned not later than Thursday, April 8th. Duties to commence on or about Monday, April 19th. By order.

P. M. MACCOLL, House Governor.

The Central Midwives Board for Ireland invite applications from registered Medical Practitioners, men or women (stating special qualifications), who are willing to serve and act as Examiners in Midwifery when required by the Board.—Full particulars can be obtained from the Secretary, Central Midwives Board, 33, St. Stephen's Green, Dublin.

The Governments of the Straits Settlements and FEDERATED MALAY STATES require the services of Thirty-three MEDICAL OFFICERS. The salary offered is $440 a month for the first year, $460 for the second, and $480 for the third year.

In all cases the appointments are on probation for the first three years, after which Medical Officers may be placed on the permanent and pensionable establishment. Subject to passing a strict efficiency bar before rising above $600 per month, salaries will thenceforward be at the rate of $500 a month, rising by annual increments of $25 a month to $800 a month. Promotion to posts above this maximum will be by selection.

Officers having Specialist qualifications of an approved type will enter the scale of salary at $550, rising by $25 a year to $600 per month during the first three years; after which, if their appointments are made permanent and they pass the efficiency test, their salary will rise, as in other cases, to $800 a month.

No duty allowance is paid; there is at present a strictly temporary bonus, to meet the increased cost of living, of 10 per cent. on the salary, payable during service in Malaya only. The exchange value of the dollar is fixed by Government at 2s. 4d. This rate is liable to alteration, but has remained constant for the past fourteen years.

Candidates must be Graduates of one of the British Universities, or hold the qualifications of the College of Surgeons and Physicians of London, Edinburgh, or Ireland, and in some cases a diploma in Public Health. If they have not already done so, they will be required to attend a course of instruction at the London or Liverpool School of Tropical Medicine either before embarkation or during their first leave of absence in Europe. Their whole time will be at the disposal of the Government, and no private practice is allowed. The duties will be generally those of a House Surgeon attached to any of the Hospitals in the Malay Peninsula and any other duties on which in the public interest it may be desirable to employ them. Free passages (second-class by mail or first-class by other vessel) are given, with half salary from date of embarkation.

Candidates of over thirty-seven years of age will not be considered for appointment on the above terms. They may, however, be engaged on three years' agreement, renewable by consent of both parties, with salary commencing at $600 to $700 a month (according to qualifications) and rising annually by $25 a month. Such appointments will not be pensionable, and no prospect can be held out of promotion to the highest posts in the Medical Service. A bonus of two months' salary, however, will be payable for each completed year's service on termination of agreement or extended agreement.

Applications for these posts should be addressed to the Assistant Private Secretary (Appointments), Colonial Office, Downing-street, London, S.W. 1.

House Surgeon wanted for Perth ROYAL INFIRMARY. Salary £6 6s. per week, with board and residence. Applications, with testimonials, to be made to Mr. J. C. CAMERON, Solicitor, Perth.

Ministry of Pensions.— Bellahouston HOSPITAL, Glasgow.—Applications are invited for the post of RESIDENT MEDICAL OFFICER (three required) at a salary of £250 per annum, with board and residence. Preference will be given to ex-Service candidates. Apply, enclosing references, to Resident Medical Superintendent.

The Secretary of State for the Colonies is prepared to receive applications for the post of ASSISTANT MEDICAL OFFICER, British Guiana.

Salary £400 per annum, rising to £500 by annual increments of £25. There are only three appointments in this Junior Grade, and there are thirty-one appointments in Grades with salaries from £500 to £700 to which officers will be promoted from the Junior Grade as vacancies occur.

Officers are allowed private practice when acting in a Medical District. When attached to an institution at which private practice is not allowed, plainly furnished bachelor quarters are provided. The Senior officers at such institutions receive duty allowances varying from £30 to £300 per annum.

The appointment is for a term of two years, at the end of which time the officer may, if his service has been satisfactory, be appointed to the permanent and pensionable establishment.

A free passage to the Colony is provided.

Further particulars and forms of application can be obtained from the Assistant Private Secretary (Appointments), Colonial Office, S.W. 1.

No testimonials should be forwarded until an application form has been received from the Colonial Office.

Ship's Surgeon. — Messrs. Elder Dempster and Co., Limited, have a few vacancies for Surgeons in their West African Service. Pay £20 per month. Fees allowed for attendance on passengers. Length of voyage varies from six to ten weeks, according to particular route.—Apply, Medical Superintendent, Messrs. Elder Dempster and Co., Limited, Colonial House, Liverpool.

X-RAYS

THE "INSTANTA"

Direct Current INTERRUPTER

is, we believe, the only Interrupter with a motor made throughout in the same Factory, and designed expressly for the work. The interior of the break chamber is coated with a special enamel which renders it unnecessary to clean the mercury as frequently as hitherto.

These are only two of the many small details rendering the "Instanta" Interrupter the ideal type for operating Induction Coils.

ALSO

ALTERNATING CURRENT TYPE of same construction with special Synchronous motor.

Delivery from Stock for all normal supply currents.

Each instrument is provided with projecting shaft to take the Morton High Tension Rectifier for eliminating inverse current.
